Abstract

Kidney disease has been described as the neglected of the neglected chronic diseases. Many people worldwide are living with, and dying from, kidney disease and many of them, especially those in low-income countries, lack appropriate access to care. A general lack of awareness and recognition hampers the evaluation of the true global burden posed by acute and chronic kidney disease. The risk of kidney disease cuts across the spectrum of human conditions: from poverty to affluence, from overnutrition to undernutrition, from fetal health to aging, from biomedicine to traditional medicine, from communicable disease to noncommunicable, from agrarian societies to post-industrial, from lack of access to the cheapest generics to access to the most expensive therapies and from individual health care to public health policy. Risk of disease is also affected by ethnicity, gender, geography, migration, natural disasters, urbanization and war. Growing worldwide economic and health disparities, demographic migrations and transitions, unsafe working conditions and increasingly frequent environmental threats, natural disasters and pollution may all work against attempts to reduce the morbidity and mortality from kidney disease. A multisectoral approach is needed to tackle the global burden of such disease. The sustainable development goals (SDGs) emphasize the importance of a multisectoral approach to the optimization of health. Actions towards achieving all of the SDGs offer the opportunity to begin to understand, measure, prevent and treat kidney disease in all age groups, to foster innovations in treatments for such disease and to reduce the burden of such disease in future generations.
Introduction
The 17 sustainable development goals (SDGs) were adopted by the United Nations, as successors to the millennium development goals, with the broad goal of achieving healthy people living on a healthy planet.\(^1\) Although only SDG 3, that is, to ensure healthy lives and promote well-being for all at all ages, is specifically focused on health,\(^1\) achievement of all of the SDGs should have health benefits via impacts on the environment, governance and society.

The *Global action plan for the prevention and control of noncommunicable diseases 2013–2020* (hereafter called the 2013 action plan) outlined an approach to reduce the combined mortality from four major categories of noncommunicable disease, i.e. cancer, cardiovascular disease, chronic respiratory disease and diabetes, by 25% by 2025.\(^2\) Previously, these four categories had been prioritized in the 2008–2013 action plan because, collectively, they were believed to account for about 60% of global deaths and it was anticipated that a large proportion of these deaths could be prevented through elimination of shared risk factors, e.g. alcohol and tobacco use, poor diets and inadequate exercise.\(^3\) Although laudable, the 2013 action plan has been criticized for failing to acknowledge the broader drivers of the noncommunicable disease epidemics, other important noncommunicable diseases and the so-called causes of the causes of noncommunicable diseases and failing to place sufficient emphasis on the need for coordinated multisectoral action.\(^4\) We argue that kidney disease represents one of the important noncommunicable diseases missing from the 2013 action plan and that, given the many social and structural factors that directly affect risks and outcomes of kidney disease, multisectoral action to achieve the SDGs will help prevent and control such disease (Table 1).\(^1\)

Global burden
Although often considered a comorbidity of diabetes or hypertension, kidney disease has numerous complex causes.\(^5\) Importantly, such disease has an indirect impact on global morbidity and mortality by increasing the risks associated with at least five other major killers: cardiovascular diseases, diabetes, hypertension, infection with human immunodeficiency virus (HIV) and malaria. For example, the Global Burden of Disease (GBD) 2015 study estimated that 1.2 million deaths, 19 million disability-adjusted life-
years (DALYs) and 18 million years of life lost from cardiovascular diseases were directly attributable to reduced glomerular filtration rates.6,7

The GBD 2015 study also estimated that, in 2015, 1.2 million people died from kidney failure – an increase of 32% since 2005.7 In 2010, an estimated 2.3–7.1 million people with end-stage kidney disease died without access to chronic dialysis.8 Additionally, each year, around 1.7 million people are thought to die from acute kidney injury.9 Overall, therefore, an estimated 5–10 million people die annually from kidney disease. Given the limited epidemiological data, the common lack of awareness and the frequently poor access to laboratory services, such numbers probably underestimate the true burden posed by kidney disease. It is therefore possible that, each year, at least as many deaths are attributable to kidney disease as to cancer, diabetes or respiratory diseases – three of the four main categories targeted by the 2013 action plan.2,10,11 In addition, the estimated number of DALYS attributable to kidney disease globally increased from 19 million in 1990 to 33 million in 2013.12 In 2016, the DALYs associated with chronic kidney disease, along with those associated with cardiovascular disease, cancers, diabetes and neurological disorders, were found to have increased significantly between 1990 and 2015.6 A report from the GBD 2016 study highlighted the important omission of focus on chronic kidney disease and suggested that “the SDG agenda offers at best a minimal platform for drawing attention to the health care and monitoring needs of [chronic kidney disease].”13

Kidney disease is associated with a tremendous economic burden. High-income countries typically spend more than 2–3% of their annual health-care budget on the treatment of end-stage kidney disease, even though those receiving such treatment represent under 0.03% of the total population.14 In 2010, 2.62 million people received dialysis worldwide and the need for dialysis was projected to double by 2030.8 Globally, the total cost of the treatment of the milder forms of chronic kidney disease appears to be much greater than the total cost of treating end-stage kidney disease. In 2015, in the United States of America, for example, Medicare expenditures on chronic and end-stage kidney disease were more than 64 billion and 34 billion United States dollars, respectively.15 Much of the expenditure, morbidity and mortality previously attributed to diabetes and hypertension are attributable to kidney disease and its complications.12,16
Worldwide, important risk factors for kidney disease include diarrhoeal diseases, HIV infection, low birth weight, malaria and preterm birth, all of which are also leading global causes of DALYs.\textsuperscript{12} Risks of kidney disease span the life-course and environmental, infection and lifestyle etiologies.\textsuperscript{17} If risk factors are identified early, acute kidney injury and chronic kidney disease can be prevented and, if kidney disease is diagnosed early, worsening of kidney function can be slowed or averted by inexpensive interventions, several of which are on the World Health Organization’s (WHO’s) so-called best buys list for noncommunicable disease management.\textsuperscript{18} Such interventions include counselling for cardiovascular disease, diabetes and hypertension, drug therapy, tobacco control, promotion of physical activity and the reduction of salt intake through legislation and food labelling. The timely identification and management of acute kidney injury and chronic kidney disease represent the most effective strategy to address the growing global burden sustainably.\textsuperscript{4,5} By advocating for a multisectoral approach, as a means to achieving the SDGs, it should be possible to reduce the incidence of kidney disease globally.\textsuperscript{19} We discuss the kidney-health-related opportunities offered by attempts to achieve each SDG (Table 1).

**SDGs and kidney health**

**SDGs 1, 3.8, 3.b and 10**

In high-income countries, lower socioeconomic status is associated with greater risk of end-stage kidney disease because of behavioural and metabolic risk factors and reduced access to care.\textsuperscript{20} In low- and middle-income countries, the burden posed by such poverty-related kidney disease is even greater, because of associated infections, hazardous work, poor education and poor maternal health. In all countries, poverty is associated with lack of social protection and transportation, poor housing and unemployment.\textsuperscript{20} Lack of transportation restricts access to care even when treatment costs are not a major barrier.\textsuperscript{20} Poverty and lower socioeconomic status have been specifically identified as independent risks for both incident chronic kidney disease and the more rapid progression of such disease.\textsuperscript{20} In low-income countries where treatment costs have to be paid directly by patients, a month’s supply of essential medications for the treatment of chronic kidney disease can cost up to 18 days’ wages\textsuperscript{21} and the corresponding out-of-pocket costs of dialysis, for acute kidney injury or end-stage kidney disease, are much higher.\textsuperscript{22,23} In
South Africa, where limited access to dialysis is government-funded, patients who are otherwise eligible for dialysis are routinely declined access because of their socioeconomic circumstances. For those who do access dialysis, the financial burden is exacerbated because they cannot be employed while receiving dialysis or travelling to and from the provider.

Promotion of universal health coverage should reduce the financial hardship of patients with kidney disease and improve access to kidney care. The goal of eradicating poverty spans all of the other SDGs and is fundamental to improving kidney health. In turn, achievement of each SDG promises to promote equity and reduce poverty.

**SDG 2**

Many low-income countries have problems with undernutrition and overnutrition, both are risk factors for kidney disease. Malnutrition predisposes young children to infections, e.g. diarrhoeal diseases and pneumonia, that are important risk factors for acute kidney injury. Among girls and female adolescents, undernutrition leads to underweight mothers and low-birth-weight offspring. Low birth weights, preterm births and pregnancies affected by diabetes and pre-eclampsia, which, combined, may represent up to 20% of pregnancies worldwide, are all associated with increased lifetime risk of chronic kidney disease in both mothers and children. Obesity increases the lifetime risk of end-stage kidney disease and maternal obesity is associated with adverse outcomes in pregnancy, including the gestational diabetes and preterm births that are associated with increased risk of chronic kidney disease.

Adequate nutrition is a key tool for reducing the burden of chronic kidney disease. Groups with very low incomes often live in areas where access to healthful foods is very limited or non-existent. Some population-level strategies, e.g. public education about healthful food choices, regulation of the fat, salt and/or sugar contents of food and the regulation of programmes for the provision of public and/or school meals, can all improve kidney health. Reduction in dietary salt is proposed as a cost-saving best buy with great potential to avert deaths from kidney disease. Similarly, a tax on high-sugar beverages, as introduced in Mexico, where chronic kidney disease is the second leading cause of death, can lead to sustained decreases in the purchase of taxed drinks and may reduce diabetes-related kidney disease over time.
SDG 3
SDG 3 has many links to better kidney health (Table 2) including optimization of fetal development, prevention of infections, reduction of the mortality and morbidity of cardiovascular disease and mitigation of environmental exposures. The Global Kidney Health Atlas has provided an overview of the main gaps in kidney care globally: an absence of relevant policies, shortages of essential medications, reliable epidemiological data, relevant workforce capacity, infrastructure and research capacity and a persistent reliance on out-of-pocket payments. The Atlas emphasizes the need for a health-system-wide approach to kidney care and provides a baseline against which to measure progress. Work towards reducing the global burden of kidney disease will contribute to achieving SDG 3 (Table 2).

SDGs 4 and 5
Because they are, in general, responsible for most child care and housework, women in low- and middle-income countries may face greater challenges if they have chronic kidney disease – and other noncommunicable diseases – than men with similar health problems. Heavy demands on their time may explain why, even though chronic kidney disease is more common among women than men, fewer women than men receive dialysis. Child marriage and lack of access to family planning contribute to poor maternal health and increased risk of obstetrical complications, including acute kidney injury. Among urban adults in the United States, both gender and race appeared to affect glomerular filtration rates. Achievement of equity for women worldwide should reduce the burden of kidney disease.

SDG 6
Globally, almost 800 million people lack access to safe water and 2.5 billion lack access to optimal sanitation. In low- and middle-income countries, waterborne and pestilent diseases associated with poor hygiene and sanitation are major causes of acute kidney injury and chronic kidney disease. Enteric diarrhoeal deaths, associated with lack of safe water, cause over 1 million deaths annually. Most such deaths occur in children younger than five years and many can be attributed to dehydration-related acute kidney injury. Non-enteric diseases caused by waterborne pathogens, e.g. leptospirosis and
schistosomiasis, are also major causes of kidney disease in low- and middle-income countries.34

Local availability of clean water would be expected to reduce the risk of diarrhoea-related acute kidney injury.35 Beyond infection-related kidney complications from contaminated water and poor sanitation, additional challenges exist. Water containing organic perfluoroalkyl acids and heavy metals has been associated with chronic kidney disease in several settings and pesticide-contaminated well water may contribute to the risk of some chronic kidney disease observed in Sri Lanka.36 Dehydration, in conjunction with heat stress, may have contributed to the epidemic of chronic kidney disease observed among young, economically productive male labourers in Central America and South-East Asia.36 The global burden of kidney disease should be reduced by ensuring the availability of clean water and adequate sanitation.

**SDGs 7 and 12–15**
Climate change, degradation of biodiversity, forest and land and loss of marine resources all likely increase the risk of kidney disease through multiple mechanisms – e.g. increases in food insecurity, the incidences of heat-related illness and infectious diseases and pollution.37 Deforestation and land degradation can bring humans into greater contact with vector-borne and waterborne pathogens such as enteric bacteria and other pathogens that can directly cause kidney disease, e.g. those causing dengue fever, leishmaniasis, leptospirosis, malaria, schistosomiasis, trypanosomiasis and yellow fever.38

Reducing the global burden of kidney disease in turn will also be critical for mitigating some of the environmental impacts of dialysis. Each year, for example, the haemodialysis given to more than 2 million people requires 160 billion litres of water and generates over 900 000 tonnes of – predominantly plastic – waste.39 Clean, local production of dialysis supplies, the reprocessing of dialysis filters, the reuse of dialysis water, solar-powered dialysis and waterless dialysis are all promising strategies that could reduce the environmental footprint of dialysis as well at its costs.39

**SDGs 8, 10 and 17**
Within low- and middle-income countries, access to dialysis is highly inequitable.8 Despite its relative cost–effectiveness, access to transplantation is even more inequitable
because of cultural, financial and legislative barriers and infrastructural limitations. In the face of extreme social inequalities and a demand for transplants that markedly exceeds the supply, the trafficking of kidneys and other human organs remains a major concern.

Disparities in the burden of kidney disease, which are particularly complex, arise from biological, environmental, genetic, lifestyle and sociocultural factors and need to be addressed via multilevel, systematic interventions. An example of the complexities involved has been described in the United States. There, in general, compared with other patients with similar disease, patients with chronic kidney disease from ethnic and racial minorities have delayed referral for care, lower incomes, report poorer physician–patient relationships and have less access to health care in general. The pervasive disparities in kidney disease will have to be addressed before SDGs 8, 10 and 17 can be achieved.

**SDGs 3.6, 3.d, 9 and 11**

Rapidly occurring urbanization has contributed to the rise of kidney disease and other noncommunicable diseases in low- and middle-income countries. In addition to the commonly associated lifestyle changes, e.g. a switch to high-calorie, sodium-rich diets and decreased physical activity, rapid urbanization has led to crowded cities with environmental pollution, a limited infrastructure and poor levels of sanitation and waste disposal. Such urbanization also means that more and more people are living in settings where a growing prevalence of noncommunicable diseases, e.g. diabetes, hypertension and obesity, is juxtaposed with environmental toxins and numerous infectious diseases. These changes portend a synergistic growth in the global burden of kidney disease. There may already be evidence of such growth in the ever-higher ranking of chronic kidney disease among leading cause of deaths, across all country income categories, between 1990 and 2016.

By building resilient infrastructure while promoting sustainable industrialization, it should be possible to enhance health-care access while simultaneously reducing the risk of kidney disease. In low- and middle-income countries, urban planning, to improve hygiene and sanitation and reduce population densities and the transmission of the pathogens causing enteric infections, schistosomiasis and tuberculosis, should reduce the incidence of acute kidney injury and chronic kidney disease. At the same time, by
promoting the development of parks, paths and efficient transport systems, urban planning could increase general levels of physical activity and so help reduce the risk of obesity-related kidney disease.\textsuperscript{42}

The effective prevention of chronic kidney disease will require engagement with the corporate sector, whose interests may be in conflict with those of public health.\textsuperscript{43} Novel strategies are required to create incentives for the corporate sector to promote public health.\textsuperscript{44} Even under optimal circumstances, kidney disease cannot always be prevented and strategies to reduce the economic, physical and social burdens of end-stage kidney disease are needed. Innovative mechanisms to reduce dialysis costs and make dialysis less dependent on electricity and water could multiply opportunities for access to dialysis, especially in low- and middle-income countries.\textsuperscript{39} Innovation is also required to improve access to transplantation. Although opt-out or presumed-consent strategies have been proposed as a way of increasing the supply of organs from deceased donors, they remain contentious.

Acute kidney injury after a road-traffic collision may result from rhabdomyolysis and multi-organ failure as well as blunt or penetrating kidney injury.\textsuperscript{45} Natural disasters are associated with increased rates of crush-injury-induced acute kidney injury and frequently lead to life-threatening interruptions of treatment among those with end-stage kidney disease.\textsuperscript{46} Similarly, forced migrants with chronic or end-stage kidney disease can face dangerous interruptions in their treatment or receive inadequate care,\textsuperscript{47} even in a high-income country such as the United States.\textsuperscript{48} Continued action on reducing the burden of road-traffic injuries and supporting efforts to integrate noncommunicable disease management into humanitarian relief efforts should help to reduce the burden of chronic and end-stage kidney disease.\textsuperscript{46}

\textbf{SDG 16}

Exposure to armed conflict can result in acute kidney injury caused by crush injury and rhabdomyolysis and the severity of injuries sustained in combat strongly correlates with the subsequent risk of chronic kidney disease.\textsuperscript{49} Kidney disease is common in incarcerated populations and, in terms of their kidney health, prisoners may face a triple burden: of excess risk of kidney disease and its risk factors, of barriers to preventive care for established chronic kidney disease and of the suboptimal management of end-stage
kidney disease. As an important step towards improving global health, much work is required globally to reduce conflict and disparities and enhance peace.

Policy perspective

The net health burden of kidney disease is substantial, growing and driven by complex interactions, between communicable and noncommunicable diseases, that are shaped by upstream environmental and socioeconomic disparities. Although kidney disease, whether acute, chronic or end-stage, can be extremely costly, it is also potentially preventable and adverse outcomes can often be delayed or prevented by inexpensive interventions. Kidney disease is highly prevalent, spans the life course and has substantial financial implications. Our response to such disease requires a systematic policy approach, to strengthen all relevant aspects of the health system and to facilitate integration of the promotion of kidney health within a comprehensive horizontal programme for the prevention and treatment of noncommunicable diseases (Table 2).

Within each country, the local burden and prevalence of kidney disease and its risk factors and the local capacity to identify and manage such disease must be determined, as a prerequisite for fair priority setting and appropriate policy development. Diagnosis of kidney disease is often hampered by a lack of awareness among health-care workers and at-risk communities and by inadequate and often erratic access to laboratory testing. Broad policies are increasingly being adopted globally to curb dietary intakes of fat, salt and sugar. Such policies all promise to reduce the burden of chronic kidney disease. The burden of acute kidney injury could be reduced through the ongoing commitment to reduce the transmission of the pathogens causing infectious diseases.

We need universal health coverage to tackle kidney disease successfully and ensure effective screening, prevention and early treatment. Effective and transparent policies to govern access to care for end-stage kidney disease should only be developed after there has been thorough attempt to determine the local health priorities, especially in resource-poor settings. Engagement with all relevant stakeholders and innovative financing strategies will be required to maximize equitable access to care. The bidirectional and synergistic interplay between kidney disease and all of the SGDs must be acknowledged in the development of a multisectoral approach. Policies that foster domestic and international collaboration, improve occupational and road safety, limit
organ trafficking, promote access to education and gender equality, reduce
unemployment and tackle the predicted adverse effects of climate change may all reduce
kidney disease and/or the disparities in the care for such disease. However, as noted by
the United Nations Secretary-General in December 2017, in the control and prevention of
noncommunicable diseases, “political commitments have not often been translated into
concrete action.”51 On its own, policy-making is insufficient. Monitoring the impact of
policies on kidney disease and the risk factors for such disease needs to be integrated into
existing surveillance activities. Health workers and communities must be empowered to
advocate for, and hold policy-makers accountable for, kidney health, as an important step
towards achievement of the SDGs.

<tr>
<td><strong>HIV and hepatitis-associated kidney disease, infectious glomerulonephritis</strong></td>
<td>Alcohol use and smoking are risk factors for CKD progression</td>
</tr>
<tr>
<td></td>
<td>Reduce infections transmitted by intravenous drug use</td>
</tr>
</tbody>
</table>

- Development of innovative interventions to improve labour conditions and conditions in prisons
- Provision of public education and UHC
- Development of care models integrating traditional healers
- Legislation on alcohol consumption to reduce high-risk drinking
- Development of public health policy to improve disease surveillance and the effectiveness of diagnosis and treatment
- Development of public health policy to improve disease surveillance and response to outbreaks
- UHC
- Enactment of protections for women victims of domestic violence and sexual assault
- Taking action, including legal, policy and regulatory reforms, to ensure full political enfranchisement for women
- Promotion of healthy lifestyles through education and regulation of unhealthy food consumption
- Adoption and implementation of FCTC
- Enhancement of capacity and infrastructure for detection and surveillance
- Development of care models integrating traditional healers
- Enhancement of occupational safety standards
- Development of transparent policies governing access to expensive therapies such as dialysis and transplantation
- UHC
- Enactment of protection for women victims of domestic violence and sexual assault
- Taking action, including legal, policy and regulatory policy reforms, to ensure full political enfranchisement for women
- Promotion of urban safety

<tbody>
<tr>
<td>3.6</td>
<td>By 2020, halve the number of global deaths and injuries from road traffic accidents</td>
<td>Rhabdomyolysis: Prevent rhabdomyolysis by increasing awareness and providing treatment for drug withdrawal and delirium tremens. AKI, CKD: Prevent trauma-related crush injury or blunt kidney trauma. Prevent accident-related losses in employment, increases in poverty and reductions in access to health care.</td>
<td>- Legislation and regulation of alcohol consumption&lt;br&gt;- Adoption and implementation of FCTC&lt;br&gt;- Legislation for the protection of sex workers&lt;br&gt;- Enforcement of existing traffic laws and reform of traffic laws to reduce road trauma&lt;br&gt;- Promotion of occupational safety&lt;br&gt;- Development and building of infrastructure and safe roads, with capacity to absorb urban growth&lt;br&gt;- Promotion of access to education for all and family planning, gender equity and UHC&lt;br&gt;- Strengthen legislation on access to safe abortion and the protection of sex workers</td>
</tr>
<tr>
<td>3.7</td>
<td>By 2030, ensure universal access to sexual and reproductive health-care services, including for family planning, information and education, and the integration of reproductive health into national strategies and programmes</td>
<td>Pregnancy-related: Empower women, increase spacing of pregnancies and reduce teenage pregnancies. AKI, CKD: Reduce risk of low birth weight and preterm birth, as these can adversely affect kidney health of the child.</td>
<td>- Prevention of innovative financing, regulation of the pricing of medical products and UHC&lt;br&gt;- Monitoring of catastrophic health expenditure</td>
</tr>
<tr>
<td>3.8</td>
<td>Achieve UHC, including financial risk protection, access to quality essential health-care services and access to safe, effective, quality and affordable essential medicines and vaccines for all</td>
<td>AKI, CKD: Provide universal access to basic health care and services for the diagnosis, prevention and treatment of all kidney disease and its risk factors, e.g. diabetes and hypertension.</td>
<td>- Promotion of environmental protection and safety&lt;br&gt;- Promotion of sustainable agriculture and fishing&lt;br&gt;- Commitment to combat climate change</td>
</tr>
<tr>
<td>3.9</td>
<td>By 2030, substantially reduce the number of deaths and illnesses from hazardous chemicals and air, water and soil pollution and contamination</td>
<td>CKD of unknown origin, observed in Egypt, India and Sri Lanka, and Balkan nephropathy: Reduce exposure to environmental toxins that may be associated with CKD, e.g. aristolochic acid and cadmium and others.</td>
<td>- Promotion of environmental protection and safety&lt;br&gt;- Promotion of sustainable agriculture and fishing&lt;br&gt;- Commitment to combat climate change</td>
</tr>
<tr>
<td>3.a</td>
<td>Strengthen the implementation of WHO's FCTC in all countries, as appropriate</td>
<td>CKD: Reduce tobacco smoking, a risk factor for cardiovascular disease and mortality, haematuria, low birth weight and proteinuria.</td>
<td>- Adoption and implementation of FCTC</td>
</tr>
<tr>
<td>3.b</td>
<td>Support the research and development of vaccines and medicines for the communicable and noncommunicable diseases that primarily</td>
<td>AKI: Provide and support the uptake of vaccines that can prevent diarrhoeal illness, sepsis and other infections that can cause AKI and can prevent low birth weight in pregnancy.</td>
<td>- Promotion of budget allocation for locally relevant research&lt;br&gt;- Strengthening and empowerment of local research ethics committees&lt;br&gt;- Utilization of TRIPS Agreement exemptions</td>
</tr>

affect developing countries, provide access to affordable essential medicines and vaccines, in accordance with the Doha Declaration on the TRIPS Agreement and Public Health, which affirms the right of developing countries to use to the full the provisions in the TRIPS Agreement regarding flexibilities to protect public health and, in particular, provide access to medicines for all appropriate antibiotics that can prevent AKI and glomerulonephritis.

Vaccination in pregnancy can reduce the risk of low birth weight. Vaccination during pregnancy can reduce the incidence of low birth weight. Provide affordable and sustainable access to basic medications for CKD, diabetes and hypertension and so reduce burden of end-stage kidney disease. Devise innovative ways to deliver cheaper dialysis worldwide. Promote safe and altruistic kidney donation by living donors. Improve supply from deceased donors where permissible. Stop organ trafficking.

CKD

3.c Substantially increase health financing and the recruitment, development, training and retention of the health workforce in developing countries, especially in least developed countries and small island developing states

Kidney disease awareness and capacity to treat

Improve awareness and capacity to diagnose, prevent and treat kidney disease. Train and retain health-care workers with knowledge of kidney disease.

Development of innovative financing models to reduce costs of dialysis and transplantation. Promotion of the education, licensing and registration of health-care workers and researchers. Promotion of the fair remuneration of health-care workers. Legislation to define the scope of practice of community health workers and any associated task shifting.

Train and retain health-care workers with knowledge of kidney disease.
