Risk Assessment Drafting Group	xv
Reviewers	xvii
Foreword	xxi
Abbreviations used in the text	xxiii
EXECUTIVE SUMMARY	xxv
PART 1. HAZARD IDENTIFICATION	
1.1 Historical	1
1.2 Characteristics of <i>Listeria monocytogenes</i>	1
1.3 Overview of listeriosis	2
1.4 Statement of problem and scope of risk assessment	5
PART 2. HAZARD CHARACTERIZATION	
2.1 Listeriosis	7
2.1.1 Manifestations of listeriosis	7
2.1.1.1 Systemic listeriosis	8
2.1.1.2 Febrile gastroenteritis	11
2.1.2 Foods associated with foodborne listeriosis	11
2.2 Dose-response relations	12
2.2.1 Characterization of severity and the selection of appropriate biological end points to be modelled	12
2.2.2 Factors that affect dose-response relations for <i>L. monocytogenes</i>	13
2.2.2.1 Virulence of <i>L. monocytogenes</i> isolates	13
2.2.2.2 Host susceptibility	17
2.2.2.3 Food matrix effects	19
2.2.2.4 Interaction of pathogen, host and matrix variables	20
2.2.3 Approaches to modelling dose-response relations	21
2.2.3.1 General approaches and limitations to modelling dose-response relations for foodborne pathogens	21
2.2.3.2 <i>Listeria monocytogenes</i> dose-response models developed from epidemiological data and expert elicitations	28
2.2.3.3 <i>Listeria monocytogenes</i> dose-response models developed from data derived from surrogate pathogens or surrogate animals	35
2.2.3.4 <i>Listeria monocytogenes</i> dose-response models developed from data derived from a combination of surrogate animal and epidemiological data	40

2.3 Options for hazard characterizations to be used for modelling the public health impact of <i>L. monocytogenes</i> in ready-to-eat foods	50
2.3.1 Exponential dose-response model used in the present risk assessment	51
2.3.1.1 Overview of the estimation of parameter r in the exponential dose-response model	52
2.3.2 Dose-response models for healthy and susceptible population	55
2.3.3 Differences in susceptibility to listeriosis for different human populations.	59
2.4 r-values for Risk Characterization	59
PART 3. EXPOSURE ASSESSMENT	
3.1 Introduction	65
3.2 Exposure Data	67
3.2.1 Introduction	67
3.2.2 Prevalence	68
3.3 Modelling Exposure: Approaches	68
3.3.1 Introduction	68
3.3.2 Prevalence and concentration	70
3.3.3 Conceptual model	71
3.3.4 Mathematical models	71
3.3.5 Point estimates	72
3.3.6 Distributions and stochastic approaches	74
3.3.7 Simulation modelling	75
3.3.8 Uncertainty and variability	75
3.4 Modelling the Production-to-Consumption Chain	76
3.4.1 Environmental niche	76
3.4.2 Preharvest	76
3.4.3 Production	76
3.4.4 Processing and packaging	77
3.4.5 Transportation	77
3.4.6 Retail	77
3.4.7 Home and foodservice	78
3.5 Microbial Ecology of <i>Listeria monocytogenes</i> in Foods	78
3.5.1 Introduction	78
3.5.2 Growth limits	79
3.5.3 Growth: rate, lag and maximum population density	79
3.5.3.1 Growth rate	79
3.5.3.2 Maximum concentration	82
3.5.3.3 Lag phases or recovery from injury	82
3.5.4 Death or inactivation	83

3.5.4.1 Death rates	83
3.5.4.2 Thermal inactivation	84
3.5.4.3 Freezing	84
3.5.4.4 Non-thermal inactivation	85
3.6 Summary	86

PART 4. EXAMPLE RISK ASSESSMENTS

4.1 Overview	87
4.1.1 Introduction	87
4.1.2 Approaches taken	87
4.1.3 Choice of example risk assessments	88
4.1.3.1 Example 1: Fluid milk	88
4.1.3.2 Example 2: Ice cream	88
4.1.3.3 Example 3: Semi-dry fermented meats	89
4.1.3.4 Example 4: Cold-smoked fish	89
4.1.4 Common elements used in risk assessments	89
4.1.4.1 Definition of risks that were calculated	89
4.1.4.2 Simulation modelling	89
4.1.4.3 Estimation of consumption	90
4.1.4.4 Temperature data	90
4.1.4.5 Dose-response modelling	91
4.2 Example 1. Pasteurized milk	91
4.2.1 Statement of purpose	91
4.2.2 Hazard identification	91
4.2.3 Exposure assessment results	92
4.2.3.1 Prevalence of <i>L. monocytogenes</i> at retail in pasteurized milk	92
4.2.3.2 Concentration of <i>L. monocytogenes</i> in contaminated milk at retail	92
4.2.3.3 Growth of <i>L. monocytogenes</i> in milk	94
4.2.3.4 Growth rate of <i>L. monocytogenes</i> in milk	94
4.2.3.5 Pasteurized milk storage temperature	94
4.2.3.6 Pasteurized milk storage time	95
4.2.3.7 Concentration of <i>L. monocytogenes</i> in contaminated milk at consumption	95
4.2.3.8 Consumption characteristics for milk	96
4.2.3.9 Simulated <i>L. monocytogenes</i> in contaminated pasteurized milk at consumption	98
4.2.4 Risk characterization	98
4.2.4.1 Annual illnesses per 100 000 population	98
4.2.4.2 Illnesses per 1 000 000 servings	99
4.2.5 Uncertainty and variability	99
4.2.5.1 Effects of hazard characterization's dose-response	99
4.2.5.2 Effects of estimated consumption frequency	99
4.2.5.3 Effects of estimated consumption amounts	100

4.2.5.4	Effects of <i>L. monocytogenes</i> prevalence on risks of listeriosis	100
4.2.5.5	Effects of <i>L. monocytogenes</i> concentration at retail	101
4.2.5.6	Effects of higher storage temperatures	102
4.2.5.7	Effects of longer storage times	103
4.2.5.8	Effects of growth	104
4.3	Example 2. Ice cream	104
4.3.1	Statement of purpose	104
4.3.2	Hazard identification	104
4.3.3	Exposure assessment results	105
4.3.3.1	Prevalence of <i>L. monocytogenes</i> at retail	105
4.3.3.2	Concentration of <i>L. monocytogenes</i> at retail	107
4.3.3.3	Growth of <i>L. monocytogenes</i> in ice cream	107
4.3.3.4	Consumption characteristics for ice cream	107
4.3.4	Risk characterization	110
4.3.4.1	Annual illnesses per 100 000 population	110
4.3.4.2	Illnesses per 1 000 000 servings	111
4.3.5	Uncertainty and variability	111
4.3.5.1	Effects of hazard characterization's dose-response	111
4.3.5.2	Effects of estimated consumption frequency	112
4.3.5.3	Effects of estimated consumption amounts	112
4.3.5.4	Effects of <i>L. monocytogenes</i> prevalence	112
4.3.5.5	Effects of <i>L. monocytogenes</i> concentration at retail	113
4.4	Example 3. Fermented Meat	114
4.4.1	Statement of purpose	114
4.4.2	Hazard identification	114
4.4.3	Exposure assessment	114
4.4.3.1	Production and Consumption	114
4.4.3.2	Modelling exposure	115
4.4.4	Risk characterization	120
4.4.5	Uncertainty and variability	123
4.5	Example 4: Cold-smoked fish	124
4.5.1	Statement of purpose	124
4.5.2	Hazard identification	124
4.5.3	Exposure assessment	126
4.5.3.1	Production and consumption of smoked fish products	126
4.5.3.2	Contamination rates and levels	126
4.5.3.3	Time and temperature of storage	127
4.5.3.4	Physico-chemical parameters of cold-smoked fish	127
4.5.3.5	Growth potential and microbial ecology of vacuum-packed products	127
4.5.3.6	Exposure assessment model	128

4.5.4 Risk characterization	130
4.5.4.1 Introduction	130
4.5.4.2 Assumed variables	130
4.5.4.3 Results	131
4.5.5 Uncertainty and variability	131
4.5.5.1 Consumption	131
4.5.5.2 Effect of other microbiota	132
4.5.5.3 Reality check	132
4.6 Summary	133

**PART 5. RISK CHARACTERIZATION:
RESPONSE TO CODEX QUESTIONS**

5.1 Introduction	135
5.2 Question 1	135
5.3 Question 2	140
5.4 Question 3	143
5.4.1 Growth rates in foods	143
5.4.2 Comparison of four foods	144
5.4.3 What-if scenarios	145
5.4.3.1 Milk	145
5.4.3.2 Smoked Fish	146
5.4.4 Summary	148

PART 6. KEY FINDINGS AND CONCLUSIONS

Key findings and conclusions	149

APPENDIX 5.	
BACKGROUND FOR THE COLD-SMOKED FISH RISK ASSESSMENT	255
A5.1 Estimate of global production and national and individual consumption of cold-smoked fish	255
A5.1.1 Scope	255
A5.1.2 National and global consumption characteristics	255
A5.1.3 Serving size estimates	257
A5.1.4 Reality check	259
A5.2 Description of storage temperatures	259
A5.3 Details of growth modelling	261
A5.3.1 Physico-chemical parameters	261
A5.3.2 <i>L. monocytogenes</i> growth rate model	261
A5.3.3 Lag time	261
A5.3.4 Effect of lactic acid bacteria on shelf life and <i>L. monocytogenes</i> growth potential	264
A5.3.5 Modelling the effect of lactic acid bacteria	265
A5.4 References cited in Appendix 5	267

Acknowledgements

The Food and Agriculture Organization of the United Nations and the World Health Organization would like to express their appreciation to all those who contributed to the preparation of this report. Special appreciation is extended to the risk assessment drafting group for the time and effort that they freely dedicated to the elaboration of this risk assessment. Many people provided their time and expertise by reviewing the report and providing their comments, additional data and other relevant information. Both the risk assessment drafting group and the reviewers are listed in the following pages.

Appreciation is also extended to all those who responded to the calls for data that were issued by FAO and WHO and brought to our attention data which is not readily available in the mainstream literature and official documentation.

The risk assessment work was co-ordinated by the Joint FAO/WHO Secretariat on Risk Assessment of Microbiological Hazards in Foods. This included Sarah Cahill, Maria de Lourdes Costarrica and Jean Louis Jouve in FAO and Peter Karim Ben Embarek, Allan Hogue, Jocelyne Rocourt, Hajime Toyofuku and Jørgen Schlundt in WHO. During the development of the risk assessment additional support and feedback were provided by Lahsen Ababouch and Hector Lupin, Fishery Industries Division in FAO and Jeronimas Maskeliunas, Codex Secretariat. Publication of the report was coordinated by Sarah Cahill. Thorgeir Lawrence was responsible for editing the report for language and preparation for printing.

The preparatory work and the publication was supported and funded by the FAO Food Quality and Standards Service, the FAO Fishery Industries Division and the WHO Food Safety Department.

RISK ASSESSMENT DRAFTING GROUP

(in alphabetical order)

Robert Buchanan

Center for Food Safety and Nutrition, Food and Drug Administration,
United States of America

Roland Lindqvist

National Food Administration,
Sweden

Thomas Ross

University of Tasmania,
Australia

Mark Smith

Bureau of Biostatistics and Computer Applications, Health Products and Food Branch,
Health Canada, Canada

Ewen Todd

FOREWORD

The Members of the Food and Agriculture Organization of the United Nations (FAO) and of the World Health Organization (WHO) have expressed concern regarding the level of safety of food both at national and international levels. Increasing foodborne disease incidence over the last decades seems, in many countries, to be related to an increase in disease caused by microorganisms in food. This concern has been voiced in meetings of the Governing Bodies of both Organizations and in the Codex Alimentarius Commission. It is not easy to decide whether the suggested increase is real or an artefact of changes in other areas, such as improved disease surveillance or better detection methods for microorganisms in foods. However, the important issue is whether new tools or revised and improved actions can contribute to our ability to lower the disease burden and provide safer food. Fortunately new tools, which can facilitate actions, seem to be on their way.

Over the past decade, Risk Analysis – a process consisting of risk assessment, risk management and risk communication – has emerged as a structured model for improving our food control systems with the objectives of producing safer food, reducing the numbers of foodborne illnesses and facilitating domestic and international trade in food. Furthermore, we are moving towards a more holistic approach to food safety, where the entire food chain needs to be considered in efforts to produce safer food.

As with any model, tools are needed for the implementation of the risk analysis paradigm. Risk assessment is the science-based component of risk analysis. Science today provides us with in-depth information on life in the world we live in. It has allowed us to accumulate a wealth of knowledge on microscopic organisms, their growth, survival and death, even their genetic make-up. It has given us an understanding of food production, processing and preservation, and of the link between the microscopic and the macroscopic world and how we can benefit from as well as suffer from these microorganisms. Risk assessment provides us with a framework for organizing all this data and information and to better understand the interaction between microorganisms, foods and human illness. It provides us with the ability to estimate the risk to human health from specific microorganisms in foods and gives us a tool with which we can compare and evaluate different scenarios, as well as to identify the types of data is necessary for estimating and optimizing mitigating interventions.

Microbiological risk assessment can be considered as a tool that can be used in the management of the risks posed by foodborne pathogens and in the elaboration of standards for food in international trade. However, undertaking a microbiological risk assessment (MRA), particularly quantitative MRA, is recognized as a resource-intensive task requiring a multidisciplinary approach. Yet foodborne illness is among the most widespread public health problems, creating social and economic burdens as well as human suffering, making it a concern that all countries need to address. As risk assessment can also be used to justify the introduction of more stringent standards for imported foods, a knowledge of MRA is important for trade purposes, and there is a need to provide countries with the tools for understanding and, if possible, undertaking MRA. This need, combined with that of the Codex Alimentarius for risk-based scientific advice, led FAO and WHO to undertake a programme of activities on MRA at the international level.

The Food Quality and Standards Service, FAO, and the Food Safety Department, WHO, are the lead units responsible for this initiative. The two groups have worked together to develop the area of MRA at the international level for application at both the national and international levels. This work has been greatly facilitated by the contribution of people from around the world with expertise in microbiology, mathematical modelling, epidemiology and food technology to name but a few.

This Microbiological Risk Assessment series provides a range of data and information to those who need to understand or undertake MRA. It comprises risk assessments of particular pathogen-commodity combinations, interpretative summaries of the risk assessments, guidelines for undertaking and using risk assessment, and reports addressing other pertinent aspects of MRA.

We hope that this series will provide a greater insight into MRA, how it is undertaken and how it can be used. We strongly believe that this is an area that should be developed in the international sphere, and have already from the present work clear indications that an international approach and early agreement in this area will strengthen the future potential for use of this tool in all parts of the world, as well as in international standard setting. We would welcome comments and feedback on any of the documents within this series so that we can endeavour to provide Member countries, Codex Alimentarius and other users of this material with the information they need to use risk-based tools, with the ultimate objective of ensuring that safe food is available for all consumers.

Executive Summary

This risk assessment on *Listeria monocytogenes* in ready-to-eat (RTE) foods was undertaken to (i) respond to the request of the Codex Committee on Food Hygiene (CCFH) for sound scientific advice as a basis for the development of guidelines for the control of *L. monocytogenes* in foods; and (ii) address the needs expressed by Member countries for adaptable risk assessments that they can use to support risk management decisions and to conduct their own assessments.

The risk assessment was tailored to address three specific questions posed by the 33rd session of the CCFH (CAC, 2000) namely:

1. Estimate the risk of serious illness from *L. monocytogenes* in food when the number of organisms ranges from absence in 25 grams to 1000 colony forming units (CFU) per gram or millilitre, or does not exceed specified levels at the point of consumption.
2. Estimate the risk of serious illness for consumers in different susceptible population groups (elderly, infants, pregnant women and immunocompromised patients) relative to the general population.
3. Estimate the risk of serious illness from *L. monocytogenes* in foods that support its growth and foods that do not support its growth at specific storage and shelf-life conditions.

By answering these questions, this risk assessment aims to assist risk managers in conceptualizing how some of the factors governing foodborne listeriosis interact, thereby assisting the development of strategies to reduce the rates of illness.

The risk assessment comprises the four steps of hazard identification, hazard characterization, exposure assessment and risk characterization. A quantitative approach was taken and mathematical modelling employed to estimate the risks per serving and risk to a population in a year from the selected foods. The risk assessment focused on four RTE foods in order to provide examples of how microbiological risk assessment techniques can be used to answer food safety questions at an international level. The study was limited to foods at retail and their subsequent public health impact at the time of consumption. The impact of post-retail factors that could influence the risk to a consumer, such as temperature and duration of refrigerated storage, was also examined. This was considered sufficient to address the questions posed by the CCFH within the time frame and resources available to the risk assessors, and also reflects the situation that most of the currently available exposure data for *L. monocytogenes* relate to the frequency and extent of contamination at the retail level.

HAZARD IDENTIFICATION

Foodborne listeriosis is a relatively rare but serious disease with high fatality rates (20–30%) compared with other foodborne microbial pathogens, such as *Salmonella*. The disease largely affects specific segments of the population who have increased susceptibilities. Basically, *L. monocytogenes* is an opportunistic pathogen that most often affects those with a severe underlying disease or condition (e.g. immunosuppression, HIV/AIDS, chronic conditions such as cirrhosis that impair the immune system); pregnant women; unborn or newly

delivered infants; and the elderly. *L. monocytogenes* is widely dispersed in the environment and foods. However, it was not until several large, common-source outbreaks of listeriosis occurred in North America and Europe during the 1980s that the significance of foods as the primary route of transmission for human exposure to *L. monocytogenes* was recognized (Broome, Gellin and Schwartz, 1990; Bille, 1990). An important factor in foodborne listeriosis is that the pathogen can grow to significant numbers at refrigeration temperatures when given sufficient time. Despite the fact that a wide variety of foods may be contaminated with *L. monocytogenes*, outbreaks and sporadic cases of listeriosis are predominately associated with RTE foods – a large, heterogeneous category of foodstuffs that can be subdivided in many different ways and vary from country to country according to local eating habits; availability and integrity of the chill chain; and regulations specifying, for example, the maximum temperature at retail level. Although listeriosis is a relatively rare disease, the severity of the disease and the very frequent involvement of industrially processed foods, especially during outbreaks, mean that the social and economic impact of listeriosis is among the highest of the foodborne diseases (Roberts, 1989; Roberts and Pinner, 1990). Listeriosis is mainly observed in industrialized countries and it is not known whether the differences in incidence rates between developed and developing countries reflect true geographical differences, differences in food habits and food storage, or differences in diagnosis and reporting practices.

HAZARD CHARACTERIZATION

The hazard characterization provides a description of the pathogen and host characteristics that contribute to an infection by *Listeria*, the public health outcomes of infection with this pathogen, the foods most commonly associated with listeriosis, and a description of the dose-response relationship. Various clinical manifestations are associated with listeriosis and these can be grouped in two categories: invasive listeriosis and non-invasive listeriosis. Invasive listeriosis are cases when initial infections of the intestinal tissue by *L. monocytogenes* leads to invasion of otherwise sterile body sites, such as the pregnant uterus, the central nervous system, or the blood, or combinations. Invasive listeriosis is characterized by a high case-fatality rate, ranging from 20 to 30% (Mead et al., 1999) and sequelae may follow listeriosis infections (McLauchlin, 1997), though their incidence is rarely estimated (Rocourt, 1996). Non-invasive listeriosis (referred to as febrile listerial gastroenteritis) has been observed during a number of outbreaks where the majority of cases developed symptoms of gastroenteritis, such as diarrhoea, fever, headache and myalgia, after a short period of incubation (Dalton et al., 1997; Salamina et al., 1996; Riedo et al., 1994; Aureli et al., 2000). These outbreaks have generally involved the ingestion of high doses of *L. monocytogenes* by otherwise healthy individuals. The incidence rate and factors that govern the onset of this non-invasive form are not known. As a result, this risk assessment only considered invasive listeriosis as the outcome of exposure.

Dose-response data from human volunteer studies with *L. monocytogenes* or from volunteer studies with a surrogate pathogen do not exist. Therefore dose-response relations have been developed and evaluated based on expert elicitations, epidemiological or animal data, or combinations of these. These dose-response relations, which were reviewed and summarized in this work, cover the spectrum of biological end-points, i.e. infection, morbidity and mortality, and have, to varying degrees of sophistication, been evaluated using human epidemiological data. All models assume that each microbial cell acts independently, and that a single bacterial cell has the potential to cause disease. However, none of the

available models were fully able to meet the needs of the current risk assessment in relation to the parameters examined and simplicity of calculation. For these reasons, alternative approaches were developed and evaluated for this risk assessment.

The approach used took advantage of the epidemiological data and detailed exposure assessment available in the *Listeria* risk assessment developed in the United States of America (FDA/FSIS, 2001). The model contains one parameter, r , which is the probability that a single cell will cause invasive listeriosis. This parameter was estimated from the pairing of population consumption patterns (exposure) with epidemiological data on the number of invasive listeriosis cases in the population. The estimated r -value, which will vary with the data sets used and the assumptions made, was then used in the exponential model to estimate specific risks given the number of *L. monocytogenes* consumed.

EXPOSURE ASSESSMENT

A full farm-to-fork risk assessment was not required to address the questions posed by the CCFH. Thus, the focus of the exposure assessment models was to account for changes in the frequency and extent of contamination in the food between retail marketing and the point of consumption. This simplified the modelling and reduced the model uncertainties, thereby decreasing the ranges around the final risk estimates. The models developed describe the growth or decline of *L. monocytogenes* between the time of purchase and consumption, using information and models for the growth rate and the lag time of *L. monocytogenes* as affected by storage temperature and food composition, the maximum growth of *L. monocytogenes* supported by the food, and the distribution of retail and home storage times and temperatures. Calculating the numbers of *L. monocytogenes* actually consumed also required consideration of how much of and how often the food is eaten (i.e. the size and the number of servings).

RTE foods are a broad and diverse food category, prepared and stored in different ways and under different conditions, some of which support growth of *L. monocytogenes* and others that do not support growth at specific storage and shelf-life conditions. As it was therefore not possible to consider all RTE foods, four foods – pasteurized milk, ice cream, fermented meat and cold smoked fish – were selected to illustrate how the different factors mentioned above interact to affect the risk of acquiring listeriosis. Pasteurized milk is a food that is widely consumed, has very low frequencies and levels of contamination with *L. monocytogenes* but allows growth of the organism during storage. Ice cream is similar to milk but does not permit growth of *L. monocytogenes* during storage. Fermented meat products are often contaminated with *Listeria* and are produced without any lethal processing step, but their final composition prevents growth of the microbe during storage. Cold-smoked fish is frequently contaminated with *L. monocytogenes*, has no lethal processing step and permits growth during an extended storage period.

Several “what-if” scenarios were also considered in the case of milk and smoked salmon. These hypothetical scenarios have specific changes made to one or more of the exposure factors to demonstrate how the factors interact to affect the risk. In conducting the exposure assessments for these four foods, different databases were available and the modellers used slightly different techniques. These techniques are explained in the main risk assessment document and illustrate that there are numerous approaches that may be taken depending on the available data and the judgment of the risk assessors.

The outputs from the exposure assessment included a distribution of *L. monocytogenes* in the food at the point of consumption (frequency of contamination) and also the amount consumed (number of servings per year and size of servings).

RISK CHARACTERIZATION

The outputs from the exposure assessment were fed into the dose-response model to develop the risk characterization portion of the risk assessment to calculate the probability of contracting listeriosis. The outputs are described in terms of estimates of risk per million servings for the healthy and susceptible populations. The risk per serving and number of servings were used to estimate the number of illnesses in a specified population per year.

The mean risk estimates of the number of illnesses per 10 million people per year and the risk per serving for pasteurized milk, ice cream, fermented meats and smoked fish are shown in Table 1. For milk, for example, the risk per serving was low (5.0×10^{-9} cases per serving), but the very high frequency of consumption resulted in milk making substantial contributions to the total number of predicted cases of illness. In contrast, for smoked fish the risk per serving was estimated to be high (2.1×10^{-8} cases per serving). However, consumption of this product is modest (1 to 18 servings per year), and consequently the total number of cases of listeriosis was moderate.

Table 1

The mean risk estimates of the number of illnesses per 10 million people per year and the risk per serving for four ready-to-eat foods.

Food	Cases of listeriosis per 10 million people per year	Cases of listeriosis per 1 million servings
Milk	9.1	0.005
Ice cream	0.012	0.000014
Smoked fish	0.46	0.021
Fermented meats	0.00066	0.0000025

RESPONSE TO QUESTIONS POSED BY THE CCFH

These risk assessments were used to address the specific questions posed by the 33rd session of the CCFH. The replies to these questions are summarized below.

Question 1: Estimate the risk of serious illness from L. monocytogenes in food when the number of organisms range from absence in 25 g to 1000 colony forming units (CFU) per gram or millilitre, or does not exceed specified levels at the point of consumption.

Two approaches were taken: (i) the predicted risk per serving and predicted number of cases of listeriosis annually were estimated for a “worst-case” scenario by assuming that all servings had the maximum level being considered (0.04, 0.1, 1, 10, 100 and 1000 CFU/g); (ii) a more realistic, but also more complex, approach was to use a distribution of the levels of *L. monocytogenes* in foods when consumed rather than an absolute value to estimate the risk per serving and the predicted number of cases of listeriosis annually.

Comparisons between these two approaches indicated that there were vast differences in the estimated number of cases when one considers the worst-case scenario as opposed to a

scenario that attempts to also consider the frequency and extent of contamination actually encountered in RTE foods. These two scenarios demonstrated that as either the frequency of contamination or the level of contamination increases, the risk and the predicted number of cases also increase. These scenarios assume that ingestion of a single cell has the possibility to cause illness. Thus, if all RTE foods went from having 1 CFU/serving to 1000 CFU/serving, the risk of listeriosis would increase 1000-fold (assuming a fixed serving size). Conversely, the effect of introducing into the food supply 10 000 servings contaminated with *L. monocytogenes* at a level of 1000 CFU/g would, in theory, be compensated by removing from the food supply a single serving contaminated at a level of 10^7 CFU/g.

In interpreting these results and the actual effect of a change in the regulatory limits for *L. monocytogenes* in RTE foods, one also has to take into account the extent to which non-compliance with established limits occurs. Based on data available for the United States of America, where the current limit for *L. monocytogenes* in RTE foods is 0.04 CFU/g, the estimated number of cases for listeriosis for that population was 2130 (baseline level used in the United States *Listeria* risk assessment). If a level of 0.04 CFU/g was consistently achieved, one could expect less than 1 case of listeriosis per year. This, in combination with available exposure data, suggests that a portion of RTE food contains a substantially greater number of the pathogen than the current limit and that the public health impact of *L. monocytogenes* is almost exclusively a function of the foods that greatly exceed the current limit. Therefore it could be asked if a less stringent microbiological limit for RTE foods could be beneficial in terms of public health if it simultaneously fostered the adoption of control measures that resulted in a substantial decrease in the number of servings that greatly exceeded the established limit.

To examine this concept further, a simple “what-if” scenario was developed describing the impact on public health of the level of compliance to a microbiological limit. Two often discussed limits, 0.04 CFU/g and 100 CFU/g, were examined in conjunction with different “defect rates” (a defect rate is the percentage of servings that exceed the specified limit). To simplify the model, a single level of *L. monocytogenes* contamination, 10^6 CFU/g, was assumed for all “defective” servings. This assumption focuses the scenario on the group of defective servings that is responsible for the majority of listeriosis cases. Data demonstrate that at 100% compliance, the number of predicted cases is low for both limits, with an approximate 10-fold difference between them, that is 0.5 cases versus 5.7 cases. As expected the number of cases increases with an increasing frequency of defective servings. However, it is possible that public health could be improved if an increase in the regulatory limit in RTE foods resulted in a substantial decrease in the number of servings that greatly exceeded the established limit, i.e. if the rate of compliance increased.

To summarize, the risk assessment demonstrates that the vast majority of cases of listeriosis result from the consumption of high numbers of *Listeria*, and foods where the level of the pathogen does not meet the current criteria, whatever they may be (0.04 or 100 CFU/g). The model also predicts that the consumption of low numbers of *L. monocytogenes* has a low probability of causing illness. Eliminating higher levels of *L. monocytogenes* at the time of consumption has a large impact on the number of predicted cases of illness.

Question 2: Estimate the risk of serious illness for consumers in different susceptible population groups (elderly, infants, pregnant women and immunocompromised patients) relative to the general population.

These results showed that the probability of becoming ill from ingesting *L. monocytogenes* was higher for susceptible populations (immunocompromised; elderly; and perinatal) than the general population. The probability of becoming ill was also shown to vary between the sub-groups of the susceptible population. Based on susceptibility information available from the United States of America, it was determined that the elderly (60 years and older) were 2.6 times more susceptible relative to the general healthy population, while perinatals were 14 times more susceptible. Conditions that compromise the immune system also affect susceptibility to varying extents (Table 2). These results are consistent with the physiological observation that, as an individual’s immune system is increasingly compromised, the risk of listeriosis at any given dose increases.

Table 2 Relative susceptibilities for different sub-populations based on French epidemiological data.

Condition	Relative susceptibility
Transplant	2584
Cancer-Blood	1364
AIDS	865
Dialysis	476
Cancer-Pulmonary	229
Cancer-Gastrointestinal and liver	211
Non-cancer liver disease	143
Cancer-Bladder and prostate	112
Cancer-Gynaecological	66
Diabetes, insulin dependent	30
Diabetes, non-insulin dependent	25
Alcoholism	18
Over 65 years old	7.5
Less than 65 years, no other condition	1

Question 3: Estimate the risk of serious illness from L. monocytogenes in foods that support its growth and foods that do not support its growth at specific storage and shelf-life conditions.

The risk assessment provides three approaches for answering the question: (i) the general consideration of the impact of the ingested dose on the risk of listeriosis; (ii) a comparison of four foods that were selected (according to diversity of prevalence and level of contamination, food composition and consumption patterns), in part, to evaluate the effect of *L. monocytogenes* growth or non-growth on risk; and (iii) the ability to conduct “what-if scenarios” for the evaluated foods that support growth of *L. monocytogenes*.

The results of the risk assessment show that the potential for growth of *L. monocytogenes* strongly influences risk, though the extent to which growth occurs is dependant on the characteristics of the food and the conditions and duration of refrigerated storage. Using the selected RTE foods, their ability to support the growth of *L. monocytogenes* appears to increase the risk of listeriosis 100- to 1000-fold on a per-serving basis. While it is not possible to present a single value for the increased risk for all RTE foods, because of the divergent properties of the foods, the ranges of values estimated in the risk assessment

provide some insight into the magnitude of the increase in risk that may be associated with the ability of food to support the growth of *L. monocytogenes*. Control measures that focus on reduction of both frequency and levels of contamination have an impact on reducing rates of listeriosis. Controlling growth post-processing is one of these measures.

KEY FINDINGS

The most important key findings of the risk assessment as a whole are:

- The probability of illness from consuming a specified number of *L. monocytogenes* is appropriately conceptualized by the disease triangle, where the food matrix, virulence of the strain and susceptibility of the consumer are all important factors.
- The models developed predict that nearly all cases of listeriosis result from the consumption of high numbers of the pathogen.
- Based on the available data, there is no apparent evidence that the risk from consuming a specific number of *L. monocytogenes* varies for the equivalent population from one country to another. Differences in manufacturing and handling practices in various countries may affect the contamination pattern and therefore the risk per serving for a food. The public health impact of a food can be evaluated by both the risk per serving and the number of cases per population per year.
- Control measures that reduce the frequencies of contamination will have a proportional reduction in the rates of illness, provided the proportions of high contaminations are reduced similarly. Control measures that prevent the occurrences of high levels of contamination at consumption would be expected to have the greatest impact on reducing rates of listeriosis.
- Although high levels of contamination at retail are relatively rare, improved public health could be achieved by reducing these occurrences at manufacture and retail in foods that do not permit growth. In foods that permit growth, control measures such as better temperature control or limiting the length of storage periods will mitigate increased risk due to increases in *L. monocytogenes*.
- The vast majority of cases of listeriosis are associated with the consumption of foods that do not meet current standards for *L. monocytogenes* in foods, whether that standard is zero tolerance or 100 CFU/g.

LIMITATIONS AND CAVEATS

- The risk assessment focuses on four RTE foods and only examines them from retail to consumption.
- The risk characterization results are subject to uncertainty associated with a modelled representation of reality involving simplification of the relationships among prevalence, cell number, growth, consumption characteristics and the adverse response to consumption of some number of *L. monocytogenes* cells. However, the modelling is appropriate to quantitatively describe uncertainty and variability related to all kinds of factors and attempts to provide estimates of the uncertainty and variability associated with each of the predicted levels of risk.
- The amount of quantitative data available on *L. monocytogenes* contamination was limited and restricted primarily to European foods.
- Data on the prevalence and number of *L. monocytogenes* in foods came from many different sources, which adds to uncertainty and variability. Also, assumptions had to be made with regard to distribution of the pathogen in foods.
- The data used for prevalence and cell numbers may not reflect changes in certain commodities that have occurred in the food supply chain during the past ten years.
- The consumption characteristics used in the risk assessment were primarily those for Canada or the United States of America.
- The r-values and their distributions were developed using epidemiological data on the current frequency of *L. monocytogenes* strain diversity observed, with their associated virulence. If that distribution of virulence were to change (as reflected by new epidemiological data), the r-values would have to be re-calculated.
- There is uncertainty associated with the form of the dose-response function used, and with the parameterization. Also, the dose-response section of the hazard characterization is entirely a product of the shape of the distribution of predicted consumed doses in the exposure assessment component of the *Listeria* risk assessment undertaken in the United States of America (FDA/FSIS, 2001). Therefore its validity is dependant on the validity of the FDA/FSIS exposure assessment, and changes to that exposure assessment should lead directly to changes in the parameter, r.
- Predictive modelling was used to model the growth of *L. monocytogenes* in RTE foods, between the point of retail and the point of consumption, and the exposure assessment was based on information derived from those models. It is known that models may overestimate growth in food, and so reliance on such a model can result in an overestimation of the risk.

CONCLUSION

This risk assessment reflects the state of knowledge on listeriosis and on contamination of foods with *L. monocytogenes* when the work was undertaken, in 2002. New data is constantly becoming available, but in order to complete this work it was not possible to incorporate the very latest data in the risk assessment. A future iteration of the work would incorporate such new data.

The risk assessment provides an insight into some of the issues to be addressed in order to control the problems posed by *L. monocytogenes*, and approaches for modelling a system to evaluate potential risk management options. It addresses the specific questions posed by the CCFH and provides a valuable resource for risk managers in terms of the issues to be considered when managing the problems associated with *L. monocytogenes*, and alternative or additional factors or means to consider when addressing a problem. For example, if a limit is being established, then the technical feasibility of achievable levels of compliance must also be considered. While the available data were considered adequate for the current purposes, the risk assessment could be improved with additional data of better quality for every factor in the assessment. For example, quantification provides new perspectives on the risk posed by exposure to different doses of *L. monocytogenes*. The gaps in the database have been identified and could be used as a basis for establishing priorities for research programmes. The risk assessment improves our overall understanding of this issue and can therefore pave the way for risk management action to address this problem at the international level.
