HEALTH CARE FACILITIES  Preliminary findings – initial review

Key messages

**Health gains/risks**

- While hospitals and health clinics are not a specific focus of mitigation assessment by the Intergovernmental Panel on Climate Change, adoption of safe and sustainable building measures by health facilities will offer more health co-benefits than the same measures applied to other commercial buildings. This is partly due to health facilities’ large demands for reliable energy, clean water and temperature/air flow control in treatment and infection prevention. Significant health gains also can be expected from specific interventions; for instance, the use of natural ventilation is both an effective energy-saving and infection-control measure.

- Resilience of health care services may be enhanced through use of (clean) onsite energy co-generation that ensures more reliable energy supply in cities where frequent energy outages occur, and in emergencies.

- Access to health care can be enhanced and made more reliable through off-grid renewable energy systems. Particularly in remote, resource-poor settings, renewable energy sources can supply basic electricity for life-saving procedures that might not otherwise be feasible.

- Health risks to health workers, patients and communities will be reduced by improved management of health care and waste – and so will the carbon footprint. Some 15–25% of health care waste is infectious waste; 3% is chemical or pharmaceutical waste; radioactive/cytotoxic waste accounts for less than 1%. Scavenged needles and syringes from dump sites represent health threats, as do dioxins, furans and other toxic pollutants emitted by poor incineration. Better management of solid, liquid and gaseous health care products, as well as emissions from infectious, chemical and radioactive agents, can reduce exposure to risks of hepatitis B/C and HIV infections as well as to reproductive problems and cancers. Improved waste treatment measures can reduce the carbon footprint of such treatment and of energy required for water supply (resource extraction).

- The health care sector is well-positioned to “lead by example” in terms of reducing climate change pollutants and by demonstrating how climate change mitigation can yield tangible, immediate health benefits.

**“Win-win” strategies for health care services and mitigation**

- Water conservation, safe onsite water storage and rainwater harvesting. Large quantities of water and special water treatment are required for many health care procedures, such as renal dialysis, burn care and cleaning of medical devices. Many rural health facilities lack piped water. Water management is thus important to reduce health risks in care facilities, as well as water-borne disease in general. Water efficiencies can help improve water access while reducing carbon-intensive water extraction and ecosystem degradation. Rainwater harvesting is one conservation measure.

---

*See also Table 1.*
widely promoted in WHO's South-East Asia Region. While rainwater, like other sources, may require treatment, harvested rainwater is used in a number of large urban hospitals recognized for “green” design.

• **Improved recapture and reuse of waste anaesthetic gases can provide significant climate and health co-benefits.** Waste anaesthetic gases are not only powerful global warming pollutants, they are associated with reproductive risks (spontaneous abortion and congenital abnormalities), headache, nausea, fatigue and cognitive impairment for exposed health workers. These gases need further review and discussion in mitigation analyses.

• **Well-designed telehealth schemes may reduce the travel-related carbon footprint of health care, and also improve access and outcomes for vulnerable groups.** Simple mobile phone applications supporting emergency assistance and long-distance consultation with health-care workers in remote areas are being used in many developing countries with good results. Systematic review of telehealth, telecare and home monitoring schemes has found evidence of effective management of the frail and elderly for diabetes as well as effective management of mental health conditions, cardiac disease and high-risk pregnancy monitoring. Meta-analysis also found evidence of health benefits for patients with lung diseases, diabetes and chronic wounds. At the same time, telehealth should recognize the importance of direct contact between patients and their health-care providers.

• **Procurement of products that subsequently are not used, particularly pharmaceuticals, was estimated to represent 60% of the carbon footprint of England’s National Health Service (NHS).** Better-managed procurement saves health care resources as well as reducing unnecessary exposures to chemical and biological agents and their waste products. In the NHS case, it was estimated that a 10% reduction in pharmaceuticals procurement would lead to a 2% reduction in the system’s carbon emissions.

**Health equity**

• **Siting of health-care facilities near major public transport arteries, and safe pedestrian/cycling routes** can improve safe and equitable access to facilities. Since hospitals are typically large employers, public transport and active travel routes can enhance opportunities for physical activity among health care workers and reduce emissions from travel to work.

• **Development of low-energy and no-energy medical devices can be expanded in tandem with use of renewable energy sources** (e.g. photovoltaic [PV] solar panels) to improve access to vital health services in poorly resourced settings. Examples of medical devices that can use solar power include: LED lights and lanterns, LED microscopes for improved tuberculosis diagnosis, and solar-powered, direct current (DC) vaccine-storage refrigerators. A wide array of rapid diagnostics require no energy at all to use. The US Department of Energy is currently sponsoring research on use and development of DC grids and devices for residential and small commercial applications.

---

**The climate footprint of health care facilities**

Health care facility activities have been estimated to represent 3–8% of the climate change footprint in developed-country settings such as England’s National Health Service and the United States of America. While no such health sector estimates exist elsewhere at a national level, electricity access and hospital electricity consumption data in countries of South-East Asia and sub-Saharan Africa reflect far lower energy use rates. At the same time, it has been estimated that between 200,000 and 400,000 hospitals and health clinics in developing countries have no electricity or have unreliable electric supplies.

Health care procedures also generate other greenhouse gases, including nitrous oxide, refrigerants and waste anaesthetic gases. Inhaled anaesthetics (e.g. nitrous oxide, desflurane, isoflurane and sevoflurane) may have large global warming potentials (GWPs). Health facility use of water and transport services, as well as health care waste disposal, all have a carbon footprint insofar as these consume energy and/or generate emissions of CO₂ as well as other climate change agents.

---

b Global warming potential (GWP) for a particular greenhouse gas is described by the United States Environmental Protection Agency (USEPA) as “the ratio of heat trapped by one unit mass of the greenhouse gas to that of one unit mass of CO₂ over a specified time period.” (www.epa.gov). For more detail see: Contribution of Working Group I to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change, 2007.
This analysis reviews mitigation measures relevant to health care facilities, as covered in assessments for commercial buildings and for industry by the Intergovernmental Panel on Climate Change (IPCC), *Working Group III – Fourth Assessment Report* (2007). Mitigation measures have been examined in terms of: their direct impacts on the delivery of health care services; on environmental and occupational health for health workers, patients and communities; and indirect benefits such as improved resilience of health care facilities and more reliable energy provision. In addition, this analysis looks at how health equity is impacted by certain mitigation strategies. For instance, in poor, off-grid rural clinics, more use of renewable energy sources, along with more efficient medical devices, may increase access to and reliability of health care. While most of the focus is on IPCC-assessed mitigation strategies, some strategies not explicitly noted by IPCC also are considered, when these take advantage of unique health care sector opportunities to generate health and environment co-benefits.

This report does not analyse the impact of climate change on health care delivery. While climate change has a significant impact on public health responses to changing patterns of disease transmission and natural disasters, this is largely an “adaptation” issue, covered by a considerable body of ongoing work both in WHO, the United Nations system and IPCC.\(^\text{37,38,39}\) This review, in contrast, is focused on mitigation, which is less explored. Of course, where mitigation measures can also improve the health sector’s adaptive response to climate change, these co-benefits are described.

**Health sector activities considered**

WHO defines the health care system as “all organizations, institutions, and resources that are devoted to producing health actions.” A health action is defined as any effort, whether personal health care, public health service or inter-sectoral initiative, whose primary purpose is to improve health.\(^\text{40}\) In practice, the health care sector includes such a wide variety of practices and activities that precise definition of the sector’s boundaries across countries and cultures can probably never be conclusive.\(^\text{41}\) This document focuses on health care facilities, including those that provide direct health treatment to patients. This includes hospitals and health care clinics, but not health clubs, home-based health care or pharmaceutical manufacturing. The focus is largely on facility-based services and not outreach such as vaccine and bednet distribution campaigns, vector management and emergency relief. Health care facilities are examined because they represent a major part of the overall sectoral activities and of the sector’s climate and environment impacts.

**Mitigation strategies reviewed**

The potential health impacts of key IPCC-reviewed strategies were appraised in the light of health-based evidence identified in a review of nearly 300 peer-reviewed articles and reports relating to health facility building design and energy efficiency, as well as to environmental/occupational health determinants in health facilities. The health effects of IPCC-reviewed mitigation strategies were assessed in terms of their impacts on:

- environmental and occupational determinants of health among health workers, patients and communities;
- improved health care facility access to reliable energy and, where relevant, other energy-linked resources vital to basic health care provision, particularly clean water;
- potential overall savings in health care resources that presumably provide resources for other health care purposes.

Integral to all measures was consideration of how mitigation measures can improve health equity through better access to care.

**BACKGROUND AND RATIONALE**

Health care is a major economic sector worldwide. In 2007, world health expenditures totaled US$ 5.3 trillion, or US$ 639 per person per year\(^\text{44,35}\), or roughly 8–10% of global GDP.\(^\text{46}\) Modern health care procedures also require many energy-intensive processes in terms of water, lighting, heating, cooling and ventilation as well as waste disposal. Mitigation measures that use resources more efficiently save health sector resources in the short and long term, and also enhance provision of health care services and benefit health directly and indirectly. Until now, IPCC-reviewed mitigation strategies for commercial buildings and industry have not specifically focused on the health care sector or its facilities. However, this sector is worthy of special attention due to its size, its growth, and its direct impacts on health. As perceived leaders in health-promoting activities and behaviour, health policy decision-makers also can be expected to lead initiatives that address global environmental health now and in the future.

WHO is thus undertaking a review of potential health co-benefits (and where relevant, risks) of mitigation strategies relevant to health care facilities. Many of the strategies are common to commercial buildings and industry, and were considered and documented by the IPCC’s *Fourth Assessment Report* in those chapters. Certain strategies, however, apply in different ways to the health care sector due to its unique needs. Moreover, the health care sector offers some unique opportunities for mitigation overlooked by other reviews.
SUMMARY OF INITIAL FINDINGS

A range of mitigation measures common to buildings and industry may have special relevance to health care facilities for provision of improved services. Key messages reflect some of the most policy-relevant findings. Table 1 provides a more systematic summary of health impacts and co-benefits of IPCC-reviewed and other targeted measures, including:

- building-related energy efficiencies;
- on-site energy generation and storage;
- intensified development and use of low-energy medical devices;
- appropriate use of natural (mixed-mode) ventilation and natural daylighting;
- on-site rainwater capture and treatment, as appropriate;
- waste/sewage treatment as appropriate;
- siting of facilities to improve access to health care by mass transport and active transport;
- materials procurement and waste reduction/management strategies;
- expanded use of telehealth and other home-care strategies

- reduction, recapture/reuse of inhaled anaesthetics.

Finally, there is a need for more systematic measuring and benchmarking of health sector energy consumption and emissions, as well as of overall environmental performance in the context of “greener” facility designs and use of renewable energy sources. Systematic assessment of the actual health impacts and economic impacts of energy-saving technologies, designs and devices also is needed to identify the most cost-effective and practical strategies, particularly for low-resource settings.

Major health organizations, beginning with WHO, have affirmed that climate change is a public health concern. Given the health sector’s leadership role, it must demonstrate to the world how climate change can and should be addressed. A full report on the review will be published in the spring of 2011.

<td>Reduced-energy devices (IPCC chapter 6)42</td>
<td>Non-electric medical devices (e.g. rapid diagnostics). Direct-current devices (e.g. direct current (DC) refrigerators and ultrasound devices, LED lights and microscopes). Energy efficient appliances: right-sizing, match and numbers; reduced standby losses.</td>
<td>Reduced emissions from energy use, fuel production and transport.</td>
<td>Health systems: Energy and operations savings, energy security, improved functionality at night (due to lighting) and device reliability46,47. Environmental effects: Decreased CO₂ emissions from energy device/appliance usage42. Disease/injury risk reduction: Improved diagnosis of tuberculosis with low-energy LED microscopes, anecdotal evidence of improved management of rural childbirth and health clinics with solar powered-LED lights/lanterns45,46,48. Health equity: Increased access to health care,46 energy security.</td>
<td>Health sector and medical device sector investment in R&amp;D for DC-powered and low-energy devices. Management capacity for energy efficiencies.</td>
</tr>
<tr>
<td>Facility wastewater and solid waste management (IPCC chapter 10)50</td>
<td>Advanced autoclaving of infectious health care waste to reduce volume and make it suitable for municipal disposal51. On-site wastewater pretreatment and sanitation improvements52,54. High-heat incineration of pharmaceuticals with pollution scrubbers53.</td>
<td>Reduced energy expenditure for waste and water treatment Reduced greenhouse gas (GHG) footprint from waste treatment processes (e.g. more efficient incineration) in some settings Reduced aquifer and ecosystem damage from sewage/waste disposal.</td>
<td>Health systems: Savings in waste/water disposal fees, reduced waste volumes, improved compliance with local air quality regulations/guidelines. Environmental risks: Improved hygiene around facility, reduced methane and other emissions52,55. Disease risks and health equity: Reduced risks of exposure to infectious agents, and to diarrhoea and other water-borne diseases (cholera, etc.) for those living downstream of health facilities56,57.</td>
<td>Infrastructure retrofit and financing. Inadequate or absent community waste treatment and wastewater treatment systems downstream.</td>
</tr>
<tr>
<td>Reduced GHG emissions from anaesthesia gas use and disposal7</td>
<td>Waste anaesthetic gas recapture and scavenging55.</td>
<td>Reduced direct emissions from anaesthesia gas waste.</td>
<td>Health systems: Anaesthesia cost savings with reuse. Environmental risks: Reduced anaesthesia emissions. Disease risk: Reduced health risks (reproductive, nervous system, cognitive disorders) for health workers exposed to gas. Health equity: Improved health worker productivity.</td>
<td>Infrastructure limitations, technology availability, limited expertise, ability to procure and secure financing.</td>
