---

**Additional information**

This vaccine conforms to the World Health Organisation (WHO) requirements and contains no preservative. The antibody concentration achieved by the immunisation falls gradually; booster doses are therefore required to maintain immunity. All immunisations and all immunoglobulins administered should be entered by the doctor, with the name of the preparation (proprietary name) and Lot. No., in the international immunisation record. Optimal immunity will only be conferred if the full immunisation schedule is completed.

---

**Active substance:** Inactivated rabies virus

**Composition**

One vial of powder and solvent for solution for injection for one immunisation dose (1 ml) contains: inactivated rabies virus (strain Flury LEP), potency ≥ 2 IU.

Host system: primary chicken fibroblast cell cultures

**Other ingredients:** TRIS-(hydroxymethyl-)aminomethane, sodium chloride, EDTA (Titriplex III), potassium-L-glutamate, polyethylene, saccharose, water for injections

**Presentation and contents by weight, volume or number of items**

Pack contains:

- One vial of lyophilate (powder), a clear colourless solution is obtained.

Pack contains:

- 30 ampoules, each containing 1 ml water for injections
- One disposable syringe

Pack contains:

- 30 vials, each containing 1 ml water for injections

**Substance or indication category**

**Vaccines**

**Name and address of the holder of the marketing authorisation**

Novartis Vaccines and Diagnostics GmbH & Co. KG

**Indications**

Active immunisation against rabies.

a) Pre-exposure immunisation (preventative, prior to exposure). Immunisation prior to possible infection with rabies, particularly for vets, veterinary medicine students, animal keepers, hunters, forestry workers, animal handlers, butchers, personnel in rabies research laboratories etc., or prior to visits to areas in which rabies is endemic (rabies infected areas).

b) Post-exposure treatment (after exposure). Treatment after contact with animals which are rabid or suspected to be rabid, or after contact with an inoculated rabies carcass.

**Contraindications**

a) Immunisation prior to exposure.

- It is advisable to avoid pre-exposure (prophylactic) immunisation in individuals with acute disorders requiring treatment.
- If complications arise after vaccination, this should be considered a contraindication for further immunisation of the same vaccine, until the causes of the complications have been clarified.
- In individuals with known allergy to one of the constituents of Rabipur, use of this vaccine is contraindicated.

b) Treatment after exposure. In view of the fact that rabies is a fatal disease, there are no contraindications to immunisation after suspected exposure (see section “Special precautions for use”).

**Pregnancy and breast-feeding**

No cases of harm attributable to use of this vaccine during pregnancy have been observed to date in mothers or children. It is not known whether Rabipur passes into breast milk.
Rabipur Product Summary File

No risk to the breast-feeding infant has been described to date.

It is advisable to carefully weigh expected benefits against potential risks prior to pre-exposure (prophylactic) immunisation with Rabipur during pregnancy and breast-feeding.

Special precautions for use

There is no, as a rule, an increased risk during immunisation with Rabipur in subjects who state that they are ‘allergic to chicken protein’ or who exhibit a positive reaction in the chicken protein skin test.

In the extremely rare cases in which subjects have reacted with clinical symptoms such as urticaria (nettle rash), lip and epiglottis oedema (inflammatory swelling of the lips and larynx region), laryngo- or bronchospasm (spasm of the glottis or bronchial muscles), a fall in blood pressure, or shock after eating chicken protein, the immunisation should be conducted only under close clinical monitoring, and with the appropriate facilities for emergency treatment available.

Rabipur contains polygeline and may contain residual amounts of the antibiotics amphotericin B, chloramphenicol, neomycin and this could potentially cause allergic reactions.

In patients with known hypersensitivity to constituents of the vaccine receiving post-exposure treatment, appropriate medical treatment addressing anaphylactic shock should always be on hand during vaccination, or alternatively another equivalent modern cell culture rabies vaccine should be used.

Minor infections (even with subfebrile temperatures [≥ 38.5 °C]) are not a contraindication, nor is possible contact with individuals suffering from infectious diseases.

Do not administer by intravascular injection!

If the vaccine is inadvertently administered intravascularly (in a blood vessel), there is a risk of adverse reactions, with shock potentially occurring in extreme cases. Appropriate emergency measures to prevent shock must be taken immediately.

Do not mix vaccine with rabies immunoglobulin in the same syringe.

After contact with animals which are suspected carriers of rabies, it is essential to observe the following procedures:

Immediate wound treatment

First aid: In order to remove as much of the rabies virus as possible, immediately cleanse the wound with soap and flush thoroughly with water. Then treat with alcohol (70%) or an iodine tincture.

Where possible, wounds should not be closed with a suture, or only sutured to secure apposition. Prophylaxis against tetanus should be administered when necessary.

In cases in which simultaneous administration of vaccine and immunoglobulin is indicated, as much of the recommended dose of human rabies immunoglobulin as anatomically feasible should be applied as deeply as possible in and around the wound. Any remaining immunoglobulin should be injected intramuscularly at a site distant from the site of vaccine administration, preferably intragluteally (in the gluteal muscle).

Interactions

In patients receiving immunosuppressive therapy (treatment which reduces the defence system of the body), or with congenital or acquired immunodeficiency, the response to the vaccination may be reduced or uncertain (see also “Dosage and administration”). Administration of immunosuppressive medication and antimalarial compounds during treatment after exposure should be avoided.

Rabies immunoglobulins should only be administered at the recommended dose. The immunoglobulins should neither be given at higher nor lower doses than those recommended, nor should they be repeatedly administered, as this may reduce the effects of rabies vaccine given at the same time.

Time intervals to be observed before other vaccinations are given

It is not necessary to observe an interval with regard to other vaccinations.

Dosage and administration

Dosage

With Rabipur, it is possible to vaccinate persons of any age group. The recommended single dose is 1 ml.

Pre-exposure immunisation (prior to exposure)

Immune protection according to A (see Table 1).

One vaccination (1 ml) on days: 0, 7 and 21 or 28.

Booster doses

International recommendations (WHO, ACP-US) are as follows:

• For persons at consistent risk, evaluate the rabies virus neutralizing antibody titres by VNT, every 4 months.

• For persons at frequent risk, the WHO recommends antibody titre estimations every year, whereas the ACP advocates testing every 2 years.

If titres are below 0.5 IU/ml at any time, one booster dose should be administered.

Considering the long term satisfactory antibody titres observed with Rabipur, if serological tests cannot be conducted due to cost considerations or inaccessible medical facilities, a booster dose one year after primary immunisation followed by one dose every 5 years would be advisable.

Post-exposure treatment (after exposure)

Begin with the course of immunisation immediately. For “immediate wound treatment”, see “Special precaution for use”!

For indications for use, see Table 1.

1. Unimmunised or incompletely immunised individuals (including those who have previously received fewer than 3 doses of vaccine, or who have received a vaccine of doubtful potency or origin):

Treatment according to schedule B or C (see also Table 2)

One single dose of vaccine on days: 0, 3, 7, 14, 28 (5-dose schedule).

As an alternative to the above mentioned 5-dose schedule, the World Health Organisation (WHO) also recommends the abbreviated 2-1-1 regimen as being effective:

Two doses on day 0 (one dose given into the right and one dose into the left deltoid muscle [upper-arm muscle] or, in small children, one dose each into the anterolateral region of the right and left thigh), and one dose each on days: 7 and 21 (see also Table 2, schedule C).

In all, injuries caused by rabid animals or animals suspected to be rabid, or after contact between the saliva of these animals and the mucous membranes or damaged skin of the patient (see Table 1), the 5-dose schedule or 2-1-1 schedule along with additional passive immunisation are required (see Table 2, schedule C). 20 IU/kg bodyweight (BW) of human rabies immunoglobulin or 40 IU/kg of equine rabies immunoglobulin are to be given once at the time of the first vaccination. As much of the rabies immunoglobulin preparation as is anatomically feasible should be applied as deeply as possible in and around the wound. Any remaining rabies immunoglobulins should be administered intramuscularly (preferably intraglottically) at a site distant from the site of the vaccine injection.

If rabies immunoglobulin is not available at the time of the first vaccination it must be administered no later than 7 days after the first vaccination since later administration would result in interference with antibody formation.

Rabies immunoglobulin should not be used at the recommended dose.

The recommended immunoglobulin dose should neither be increased, nor decreased, nor should rabies immunoglobulin administration be repeated (for further details refer to the manufacturer’s instructions).

The immunisation schedule must be followed exactly, even if considerable time has elapsed since exposure.

In subjects at particularly high risk of contracting rabies infection (e.g. with multiple wounds, particularly on the head or other markedly innervated parts of the body), or for those who have delayed initiation of treatment, the patient must be vaccinated on each of the days: 0, 3, 7, 14, 28. Additionally the initial immunisation dose should be doubled: a single dose of vaccine should be given by injection as soon as possible after exposure into the right deltoid and another single dose into the left deltoid muscle, or in small children, a single dose given into the anterolateral region of the right thigh with another single dose given into the left thigh.

Previously fully immunised individuals

Patients who have previously received a complete course of primary immunisation (pre- or post-exposure) should receive two doses of Rabipur, one on each of days 0 and 1, respectively. This is independent of the interval to the last immunisation. No administration of rabies immunoglobulin is required.

Immunocompromised individuals

Patients receiving immunosuppressive therapy, or who have congenital or acquired immunodeficiency, should be vaccinated once on each of the days: 0, 3, 7, 14, 28. In addition, the initial immunisation dose (day 0) should be doubled with a single dose of vaccine being administered as soon as possible after exposure into each of the right and left deltoid muscles (upper-arm muscle) or, in small children, into the anterolateral region of each of the right and left thighs.

If immunocompromised patients (with impaired defence system) are treated after exposure to rabies, it is advisable that the antibody titre be measured 14 days after the first dose. If a titre of at least 0.5 IU/ml, which is considered adequate to confer protection, is not present, a dose of vaccine should be immediately administered into each upper-arm muscle (or into each thigh in the case of small children). Depending on the immunisation status of these patients, additional doses may be necessary to achieve appropriate antibody titres in serum (for information on immunoglobulin administration see Section 5: "Unimmunised or incompletely immunised individuals").

Method and duration of administration

The hypodermic should be reconstructed immediately using the disinsected needle, and carefully aseptically prior to injection. The reconstructed vaccine should be used immediately.

Rabipur must be given by intramuscular injection into the deltoid muscle (upper-arm muscle), or into the anterolateral region of the thigh in small children. The vaccine must not be given by intratrigluteal (in the gluteal muscle) injection.

The vaccine must not be administered by intravascular (in a blood vessel) injection!

Undesirable effects

If you develop side effects, especially side effects which are not mentioned in this package leaflet, please inform your doctor or pharmacist.

Mild reactions at the injection site, such as pain, redness, swelling or induration are possible. More marked local reactions, sweating, chills, paraesthesias and allergic reactions; these require treatment immediately.

Possible contact with individuals suffering from infectious diseases.

There have been isolated reports of inflammatory and demyelinating neurological disorders, such as progressive ascending paralysis (Guillain-Barré syndrome) or optic neuritis in individual cases. On the basis of currently available data, the possibility cannot be completely excluded that in rare cases immunisation may induce an acute episode in patients with an autoimmune disorder (such as multiple sclerosis) or with an appropriate genetic predisposition. However, there is no evidence of an increased frequency of autoimmune disorders after immunisation.

Storage and shelf life

Rabipur should be stored at +2 to +8 °C.

Rabipur should not be used after the expiry date printed on the pack and container.

The vaccine should be used immediately after reconstruction.

Store out of reach of children!
