Influenza at the human-animal interface

Summary and assessment as of 15 February 2013

Human infection with avian influenza A(H5N1) viruses and associated animal health events

From 2003 through 15 February 2013, 620 laboratory-confirmed human cases with avian influenza A(H5N1) virus infection have been officially reported to WHO from 15 countries, of which 367 died. Since the last update on 16 January 2013, ten new laboratory-confirmed human cases with influenza A(H5N1) virus infection were reported to WHO.

Since 16 January, Cambodia reported seven new human cases with influenza A(H5N1) virus infection including six fatal cases. These cases come from four provinces all located in southern Cambodia. These cases do not seem to be linked epidemiologically, and most had contact with sick poultry in the village. Enhanced surveillance has been put in place and did not detect additional cases linked to these cases. Current evidence does not support human-to-human transmission. It has been suggested that the A(H5N1) virus is endemic in poultry in Cambodia¹, and that there is more poultry and human movement around the Lunar New Year. As such, additional sporadic human cases might be expected.

Egypt has reported one new human case with influenza A(H5N1) virus infection in Behera Governorate. The A(H5N1) virus is also endemic in poultry in some areas of Egypt, and additional sporadic human cases are possible.

On 10 February 2013, China reported 2 new human cases of influenza A(H5N1) virus infection. Both remain in critical condition. The cases come from the same province but do not seem to be epidemiologically linked. Neither had documented contact with sick or dead poultry. Contact tracing and follow up is on-going but no additional cases have been identified. The last official report of A(H5N1) in poultry in mainland China was from Guangdong Province in September 2012.

Public health risk assessment of avian influenza A(H5N1) viruses: Any time influenza viruses are circulating in poultry, sporadic infections or small clusters of human cases are possible especially in people exposed to infected poultry kept in households. However, currently, this H5N1 virus does not appear to transmit easily among people and therefore the risk of community level spread of this virus remains low. Therefore, the public health risk associated with this virus remains unchanged.

Number of Confirmed Human H5N1 Cases by month of onset as of 2013-02-15

Fig 2: Map of avian influenza H5N1 cases in humans for 2013

Areas with confirmed human cases for avian influenza A(H5N1) reported to WHO, 2013- to-date*.

*All dates refer to onset of illness
Data as of 15 February 2013
Source: WHO/IAP
**Human infection with other non-human influenza viruses**

**A(H3N2) variant virus infection**

No new human cases of influenza A(H3N2)v infection were reported from the United States of America (USA) or elsewhere.

**Overall public health risk assessment of the influenza A(H3N2)v viruses**: Further human cases and small clusters may be expected as this virus is circulating in the swine population in the USA. Continued close monitoring of the situation and the virus is warranted.

**Animal outbreaks with high pathogenic avian influenza viruses with potential public health impact**

Overall, official reports of animal influenza outbreaks have increased over the past months ([http://www.oie.int/wahis_2/public/wahid.php/DiseaseInformation/WI](http://www.oie.int/wahis_2/public/wahid.php/DiseaseInformation/WI)). This seasonal pattern is expected with the onset of winter in the northern hemisphere.

Due to the constant evolving nature of influenza viruses, WHO continues to stress the importance of global monitoring of influenza viruses in animals and people and recommends all Member States to strengthen routine influenza surveillance. All human infections with non-seasonal influenza viruses are reportable to WHO under IHR (2005).
