IRAN (Islamic Republic of)

BASIC COUNTRY DATA

Total Population: 73,973,630
Population 0-14 years: 23%
Rural population: 31%
Population living under USD 1.25 a day: 1.5%
Population living under the national poverty line: no data
Income status: Upper middle income economy
Ranking: High human development (ranking 88)
Per capita total expenditure on health at average exchange rate (US dollar): 269
Life expectancy at birth (years): 72
Healthy life expectancy at birth (years): 58

BACKGROUND INFORMATION

CL has been an increasing public health problem with several new foci identified in the last years.

Anthroponotic CL caused by L. tropica is found in Teheran as well as in some other large or medium-sized cities and their outskirts. Outbreaks are related to population increase, unplanned urban development and an increase in sandfly population [1]. In the city of Bam, there was an 8-fold increase in the number of cases over the last 5 years after the 2003 earthquake. Recent outbreaks in Bam caused 2,884 cases in 2007, 3,442 in 2008 and 1,372 in 2009, with a high rate of recidivant leishmaniasis [2].

CL caused by L. major is endemic and very common in many rural areas, especially in the plains of the northeast, near the Russian border, and in the north of the Esfahan province, in the centre of the country, but has recently spread to its southern parts and to Fars province, in southwest Iran. About 70% of CL in Iran is caused by L. major. The endemicity is so high that almost 80% of the rural population contracts the disease before the age of 10 and non-immune newcomers practically all become infected. This area may be the most important focus. However, a recent epidemiological survey in three villages in the Shiraz province, where underreporting was suspected, found a prevalence of scars of 16.2% and of infection (identified by PCR) of 23% [3].
VL is caused by *L. infantum* and is less common [4,5]. The main endemic areas are the province of Fars, in the south, and the districts of Meshkin-Shahr in the northwest. It is thought to be underreported.

HIV-*Leishmania* co-infection has been reported recently [6].

**MAPS AND TRENDS**

Cutaneous leishmaniasis
CONTROL

Notification of all forms of leishmaniasis is mandatory in Iran. A national leishmaniasis control program has been in effect since 1978. Active human case detection is regularly performed in new anthropogenic cutaneous leishmaniasis-infected areas. Case detection is passive in zoonotic cutaneous leishmaniasis areas. There is a vector control program in place that includes bednet distribution and regular insecticide spraying. The leishmaniasis reservoir control program includes the sacrifice of seropositive dogs (for VL) and regular rodent control (for CL). Due to a lack of budget and political commitment, the control program has not been efficient in controlling CL and VL.

DIAGNOSIS, TREATMENT

Diagnosis

CL: on clinical grounds, confirmation with microscopic examination of skin lesion sample. VL: confirmation by microscopic examination of bone marrow aspirate or DAT.

Treatment

CL: CL due to *L. major* is not treated when lesions are small and not facial. In all other cases: antimonials, intralesional (weekly) and cryotherapy (once every two weeks) until cured and for a maximum of 12 weeks. If needed, systemic therapy (20 mg Sb\textsuperscript{V}/kg/day for 2 weeks in CL caused by *L. major* and 3 weeks in CL caused by *L. tropica*). The cure rate is 63% with 2.8% severe adverse events. Treatment failure is especially common in CL caused by *L. tropica*. In non-responsive patients, primary resistance to antimonials has been demonstrated in both *L. major* and *L. tropica* strains.

VL: antimonials, 20 mg Sb\textsuperscript{V}/kg/day. Cure rate is 100%.

ACCESS TO CARE

Medical care is provided for free in Iran, which includes diagnosis and treatment for leishmaniasis. The Ministry of Health provided sufficient antimonials (Glucantime, Sanofi) in 2007 and 2008 to cover the needs of all patients. CL and VL can be diagnosed and treated at primary health care level; however, there is a lack of trained human resources in health centers for this purpose. The private sector is used by less than 10% of VL patients and less than 20% of CL patients. Due to several reasons, not all CL patients receive treatment. Traditional healers are often consulted in the case of CL before seeking care at health facilities. There is a lack of awareness of the nature of the disease, or patients delay seeking treatment due to the painful procedures of taking a smear for diagnosis and receiving injections of antimonials, which are not always effective in curing the disease. Other patients do not finish treatment due to financial or other constraints. There is a delay in seeking treatment for CL of approximately 1.5 months.

ACCESS TO DRUGS

No other drugs than antimonials are included in the National Essential Drug List for leishmaniasis. Meglumine antimoniate (Glucantime, Sanofi) and sodium stibogluconate (Pentostam, GSK) are the only drugs registered for leishmaniasis in Iran. Drugs for leishmaniasis are not available at private pharmacies.
