Dr. Clyde Hertzman, MD, M.Sc., FRCP C

June 2007
This summary report is based on a larger document titled the Total Environment Assessment Model of Early Child Development (TEAM-ecd) written by Arjumand Siddiqi, Lori G. Irwin and Clyde Hertzman for the Commission on Social Determinants of Health. This summary represents the efforts and commitment of many people that contributed to the TEAM-ecd document. We would like to gratefully acknowledge: the members of the Knowledge Network for Early Child Development, S. Anandalakshmy, Marion Flett, Mary Gordon, Abeba Halton, Sarah Klaus, Ilona Koupil, Cassie Landers, Beatriz Londoño Soto, Helia Molina Milman, Bame Nsamenang, Frank Oberklaid, Alia Ibrahim Shukrallah, Nurpe Ulku, Camer Vellani, Annah Wamae, and Mary Eming Young.

We would like to extend a special thanks to Meena Cabral de Mello, Senior Scientist, World Health Organization Department of Child and Adolescent Health and Technical Officer for Early Child Development, for her input, review of previous drafts, and commitment to this work. We would also like to thank the University College London Secretariat Members, Ruth Bell, Tanja Houweling, and the Geneva Secretariat Knowledge Network Coordinator, Sarah Simpson, whose patience and expertise has ensured that our work integrates with the broader goals of the Commission.

To our Commissioners, the Hon. Monique Begin, Stephen Lewis, William Foege, Alireza Marandi, and Denny Vågerö, we thank you for championing the recognition of the importance of the social determinants of health and for committing to moving this work from knowledge to action.

We would like to acknowledge the input we received from experts such as Alan Kikuchi-White, Alan Pence, and Ijig Ertem. We are also grateful to our colleagues at the Human Early Learning Partnership (HELP) for their contributions to earlier versions of the TEAM-ecd document. We are also grateful to our colleagues whose unending support made this work possible: Jacqueline Smit Alex, Leslie Fernandez, and Sophia Cosmadakis.

Finally, we want to extend a special thank you to Karyn Huemann for her editorial expertise, to Maria LeRose for her ability to synthesise complex information and make it accessible to a broad audience (www.barlettlerose.ca), to Shannon Harvey for her creative design, and to Betty Beck for her prepress/production expertise.

This work was made possible through funding provided by the Public Health Agency of Canada and undertaken as work for the Early Child Development Knowledge Network established as part of the WHO Commission on the Social Determinants of Health. The views presented in this report are those of the authors and do not necessarily represent the decisions, policy or views of the WHO or Commissioners.

Note: This report has undergone an external review process.

Abstract

This document synthesizes knowledge about opportunities to improve the state of early child development (ecd) on a global scale. In keeping with international policy standards, we define early childhood as the period from prenatal development to eight years of age. What children experience during the early years sets a critical foundation for their entire lifecourse. This is because ecd—including the physical, social/emotional and language/cognitive domains—strongly influences basic learning, school success, economic participation, social citizenry, and health. Within the work of the Commission, ecd has strong links to other social determinants of health, particularly Urban Settings, Gender, Globalization, and Health Systems. Areas of common concern with these determinants are discussed throughout this document. Research confirms a strong association between child survival and child development, such that the child survival and health agendas are indivisible from ecd. Our developmental approach to the early years includes the factors that affect child health and survival, but goes beyond these to consider how the early years can be used to create thriving global citizens. Here, we provide a framework for understanding the environments (and their characteristics) that play a significant role in influencing early development. The evidence and its interpretation is derived primarily from three sources: 1) peer-reviewed scientific literature, 2) reports from governments, international agencies, and civil society groups, and 3) a Knowledge Network of experts in ecd that is representative in both international and inter-sectoral terms. The principal strategic insight of this document is that the nurturant qualities of the environments where children grow up, live and learn—parents, caregivers, family and community—will have the most significant impact on their development. In most situations, parents and caregivers cannot provide strong nurturant environments without help from local, regional, national, and international agencies. We propose ways in which government and civil society actors, from local to international, can work in concert with families to provide equitable access to strong nurturant environments for all children globally.

Key Words: early child development; equity; social determinants of health; lifecourse; rights of the child
Early Child Development: Investment in a Country’s Future

The early years of life are crucial in influencing a range of health and social outcomes across the lifespan. Research now shows that many challenges in adult society—mental health problems, obesity/stunting, heart disease, criminality, competence in literacy and numeracy—have their roots in early childhood. Economists now assert on the basis of the available evidence that investment in early childhood is the most powerful investment a country can make, with returns over the lifecourse many times the amount of the original investment. Governments can make major and sustained improvements in society by implementing policies that take note of this powerful body of research while, at the same time, fulfilling their obligations under the United Nations Convention on the Rights of the Child.

Research now shows that children’s early environment has a vital impact on the way their brains develop. A baby is born with billions of brain cells that represent lifelong potential, but, to develop, these brain cells need to connect with each other. The more stimulating the early environment (social interaction), the more positive connections are formed in the brain and the better the child thrives in all aspects of his or her life, in terms of physical development, emotional and social development, and the ability to express themselves and acquire knowledge.

We know what kinds of environments promote early child health and development. While nutrition and physical growth are basic, young children also need to spend their time in caring, responsive environments that protect them from inappropriate disapproval and punishment. They need opportunities to explore their world, to play, and to learn how to speak and listen to others. Parents and other caregivers want to provide these opportunities for their children, but they need support from community and government at all levels. For example, children benefit when national governments adopt “family-friendly” social protection policies that guarantee adequate income for all, maternity benefits, financial support for the ultra-poor, and allow parents and caregivers to effectively balance their time spent at home and work. Despite this knowledge, it is estimated that at least 200 million children in developing countries alone are not reaching their full potential.

Political leaders can play an important role in guaranteeing universal access to a range of early child development services: parenting and caregiver support, quality childcare, primary healthcare, nutrition, education, and social protection. In the early years, the health care system has a pivotal role to play, as it is the point of first contact and can serve as a gateway to other early childhood services. To be effective, services at all levels need to be better coordinated and to converge at the family and local community in a way that puts the child at the centre.

These kinds of family-friendly policies and practices clearly benefit children and families, but they also result in economic benefits to the larger society. Globally, those societies that invest in children and families in the early years—rich or poor—have the most literate and numerate populations. These are the societies that have the best health status and lowest levels of health inequality in the world.

Success in promoting early child development does not depend upon a society being wealthy. Because early child development programs rely primarily on the skills of caregivers, the cost of effective programs varies with the wage structure of a society. Regardless of their level of wealth, societies can make progress on early child development by allocating as little as $1.00 in this area for every $10.00 spent on health and education.

Child Survival and Child Health agendas are indissoluble from Early Child Development. That is, taking a developmental perspective on the early years provides an overarching framework of understanding that subsumes issues of survival and health. A healthy start in life gives each child an equal chance to thrive and grow into an adult who makes a positive contribution to the community—economically and socially.
Executive Summary

The early child period is considered to be the most important developmental phase throughout the lifespan. Healthy early child development (ecd)—which includes the physical, social/emotional, and language/cognitive domains of development, each equally important—strongly influences well-being, obesity/stunting, mental health, heart disease, competence in literacy and numeracy, criminality, and economic participation throughout life. What happens to the child in the early years is critical for the child’s developmental trajectory and lifecourse.

The principal strategic insight of this document is that the nurturant qualities of the environments where children grow up, live and learn matter the most for their development, yet parents cannot provide strong nurturant environments without help from local, regional, national, and international agencies. Therefore, this report’s principal contribution is to propose ways in which government and civil society actors, from local to international, can work in concert with families to provide equitable access to strong nurturant environments for all children globally. Recognizing the strong impact of ecd on adult life, it is imperative that governments recognize that disparities in the nurturant environments required for healthy child development will impact differentially on the outcome of different nations and societies. In some societies, inequities in ecd translate into vastly different life chances for children; in others, however, disparities in ecd reach a critical point, where they become a threat to peace and sustainable development.

The early years are marked by the most rapid development, especially of the central nervous system. The environmental conditions to which children are exposed including the quality of relationships and language environment in the earliest years literally “sculpt” the developing brain. The environments that are responsible for fostering nurturant conditions for children range from the intimate realm of the family to the broader socioeconomic context shaped by governments, international agencies, and civil society. These environments and their characteristics are the determinants of ecd; in turn, ecd is a determinant of health, well-being, and learning skills across the balance of the lifecourse.

Economists now assert on the basis of the available evidence that investment in early childhood is the most powerful investment a country can make, with returns over the lifecourse many times the size of the original investment.

The scope of the present report is fourfold:

1. To demonstrate which environments matter most for children. This includes environments from the most intimate (family) to the most remote (global).

2. To review which environmental configurations are optimal for ecd, including aspects of environments that are economic, social, and physical in nature.

3. To determine the “contingency relationships” that connect the broader socioeconomic context of society to the quality of nurturing in intimate environments such as families and communities.

4. To highlight opportunities to foster nurturant conditions for children at multiple levels of society (from family–level action to national and global governmental action) and by multiple means (i.e., through programmatic implementation, to “child-centered” social and economic policy development).

In keeping with international policy standards, early childhood is defined as the period from birth to eight years of age.
from prenatal development to eight years of age. The evidentiary base, as well as interpretation of the body of evidence, is derived from three primary sources:

1) peer-reviewed scientific literature,
2) reports from governments, international agencies, and civil society groups, and
3) international experts in the field of ECD (including the Commission on Social Determinants of Health, Knowledge Network for ECD) that is representative in both international and inter-sectoral terms.

This evidence-based multi-sourced approach ensures that the conclusions and recommendations of this report are borne out of the perspectives of a diverse array of stakeholders and broadly applicable to societies throughout the world.

One guiding principle is an “equity-based approach” to providing nurturant environments for children everywhere. Multiple perspectives—from the provisions of human and child rights declarations to the realities reflected by research evidence—make clear the importance of equity. Programs and policies must create marked improvements in the circumstances of societies’ most disadvantaged children, not just in absolute terms, but in comparison to the most advantaged children as well.

What is now known is that, in every society, inequities in socioeconomic resources result in inequities in ECD. The relationship is much more insidious than solely differentiating the rich from the poor; rather, any additional gain in social and economic resources to a given family results in commensurate gains in the developmental outcomes of the children in that family. This step-wise relationship between socioeconomic conditions and ECD is called a “gradient effect.” However, some societies are more successful than others at “dulling” the gradient effect, thus fostering greater equity. Societies accomplish this by providing a range of important resources to children as a right of citizenship, rather than allowing them to be a luxury for those families and communities with sufficient purchasing power.

Importantly, an equity-based approach is also the successful path to creating high average ECD outcomes for a nation. Societies that demonstrate higher overall average outcomes for children are those in which disadvantaged children are developmentally stronger than disadvantaged children in other nations, whereas, in all nations, children at the higher ends of the socioeconomic spectrum tend to demonstrate relatively strong outcomes.

In this report we provide a framework for understanding the environments (and their characteristics) that play a significant role in providing nurturant conditions to all children in an equitable manner. The framework acts as a guide to understanding the relationships between these environments, putting the child at the center of her or his surroundings. The environments are not strictly hierarchical, but rather are truly interconnected. At the most intimate level is the family environment. At a broader level are residential communities (such as neighbour-hoods), relational communities (such as those based on religious or other social bonds), and the ECD service environment. Each of these environments (where the child actually grows up, lives, and learns) is situated in a broad socioeconomic context that is shaped by factors at the regional, national, and global level.

The framework affirms the importance of a lifecourse perspective in decision-making regarding ECD. Actions taken at any of these environmental levels will affect children not only in present day, but also throughout their lives. The framework also suggests that historical time is critically influential for children, large institutional and structural aspects of societies (e.g., government policy-clusters, programs, and the like) matter for ECD, and these are “built” or “dismantled” over long periods of time.

Socioeconomic inequities in developmental outcomes result from inequities in the degree to which the experiences and environmental conditions for children are nurturant. Thus, all recommendations for action stem from one overarching goal: to improve the nurturant qualities of the experiences children have in the environments where they grow up, live, and learn. A broad array of experiences and environmental conditions matter. These include those that are intimately connected to the child, and therefore readily identifiable (e.g. the quality of time and care provided by parents and caregivers and the physical conditions of the child’s surroundings), but also more distal factors that in various ways influence the child’s access to nurturant conditions (e.g., whether government policies provide families and communities with sufficient income and employment, health care resources, early childhood education, safe neighborhoods, decent housing, etc.).

While genetic predispositions and biophysical characteristics partially explain how environment and experience shape ECD, the best evidence leads us to consider the child as a social actor who shapes and is in turn shaped by his or her environment. This is known as the “transactional model,” which emphasizes that the principal driving force of child development is relationships. Because strong nurturant relationships can make for healthy ECD, socioeconomic circumstances, despite their importance, are not fate.

The family environment is the primary source of experience for a child, both because family members (or other primary caregivers) provide the largest share of human contact with children and because families mediate a child’s contact with the broader environment. Perhaps the most salient features of the family environment are its social and economic resources. Family social resources include parenting skills and education, cultural practices and approaches, intra-familial relations, and the health status of family members.

Economic resources include wealth, occupa-tional status, and dwelling conditions. The gradient effect of family resources on ECD is the most powerful explanation for differences in children’s well-being across societies. Young children need to spend their time in warm responsive environments that protect them from inappropriate disapproval and punishment. They need opportunities to explore their world, to play, and to learn how to speak and listen to others. Families want to provide these opportunities for their children, but they need support from community and government at all levels.

Children and their families are also shaped by the residential community (where the child and family live) and the relational...
communities (family social ties to those with a common identity) in which they are embedded. Residential and relational communities offer families multiple forms of support, from tangible goods and services that assist with child rearing, to emotional connections with others that are instrumental in the well-being of children and their caregivers. At the residential/locality level, both governments and grass-roots organizations also play a highly influential role. Many resources available to children and families are provided on a community level through local recognition of deficits in resources, problem-solving, and ingenuity. There are, however, inequities in ecd that are apparent between residential communities, which must be addressed in a systematic way.

“Relational community” refers to the people, adults and children, who help form a child’s social identity: tribal, ethnic, religious, and language/cultural. Often, this is not a geographically clustered community. Relational communities provide a source of social networks and collective efficacy, including instrumental, informational, and emotional forms of support. However, discrimination, social exclusion, and other forms of subjugation are often directed at groups defined by relational communities. The consequences of these forms of discrimination (e.g., fewer economic resources) can result in discernable inequities. Moreover, relational communities can be sources of gender socialization, both equitable and non-equitable. Relational communities are also embedded in the larger socio-political contexts of society; as such, reciprocal engagement with other relational groups, civil society organizations, and governmental bodies is a means of addressing the interests and resource needs of their members.

The availability of ecd programmes and services to support children’s development during the early years is a crucial component of an overall strategy for success in childhood. ecd services may address one or more of the key developmental domains (i.e. language/cognitive, social/emotional, and physical development). The quality and appropriateness of services is a central consideration in determining whether existing ecd programmes improve outcomes for children. There are principles of ecd programmes and services that are readily transferable between places; however, many programme features require tailoring to the social, economic, and cultural contexts in which they are found. ecd services may be targeted to specific characteristics of children or families (e.g., low birth-weight babies or low-income families), may occur only in some communities and locales and not others, or may be more comprehensively provided. Each of these is also accompanied by their respective benefits and drawbacks; however, the overarching goal of the global community should be to find means of providing universal access to effective ecd programmes and services. Health care systems (hcs) are key to providing many important ecd services. The hcs is in a unique position to contribute to ecd, since hcs provide facilities and services that are more widely accessible in many societies than any other form of human service, are already concerned with the health of individuals and communities, employ trained professionals, and are a primary point of contact for child-bearing mothers.

The influence of the regional and national environments is fundamental in determining the quality and accessibility of services and resources to families and communities. They are also salient for understanding the levels of social organization at which inequalities in opportunity and outcome may be manifest, and the levels of organization at which action can be taken to ameliorate inequities.

There are many interrelated aspects of regional environments that may be significant for ecd: physical (e.g., the degree of urbanization, the health status of the population), social, political, and economic. These aspects of the regional environment affect ecd through their influence on the family and neighbourhood, and on ecd services. In contrast to more intimate environments, such as the family, the significance of large environments, such as the region, is that regions have an effect on large numbers of children. Thus, changing the environment at this level can influence the lives of many children. Much more research and accumulation of knowledge is required regarding how regional
characteristics can be modified to positively influence ECD.

The most salient feature of the national environment is its capacity to affect multiple determinants of ECD through wealth creation, public spending, child- and family-friendly policies, social protection, and protection of basic rights. The chances that children will face extreme poverty, child labour, warfare, HIV/AIDS, being left in the care of a sibling, and so on, is determined, first and foremost, by the countries in which they are born.

At the level of the national environment, comprehensive, inter-sectoral approaches to policy and decision-making work best for ECD. Although ECD outcomes tend to be more favourable in wealthy countries than poor ones, this is not always the case. It is clear that a commitment of 1.5–2.0% of GDP to an effective mix of policies and programmes in the public sector can effectively support children’s early development. Those nations with less economic and political power are less free to determine their internal policy agendas, and are more influenced by the interests of the international community, including other nations and multilateral organizations. Notwithstanding this, most of the recommendations in this report are within the capabilities of any national government that meets the international criteria for a “competent authority.”

The global environment can influence ECD through its effects on the policies of nations as well as through the direct actions of a range of relevant actors, including multilateral economic organizations, industry, multilateral development agencies, non-governmental development agencies, and civil society groups. A major feature of the global environment in relation to children’s well-being is the element of power in economic, social, and political terms. Power differentials between types of actors, particularly between nations, have many consequences, including the ability of some nations (mainly resource-rich ones) to influence the policies of other nations (mainly resource-poor ones) to suit their own interests. Although power differentials may have invidious effects on ECD, they can be exploited for the benefit of children, too.

Requiring a minimum level of government spending on ECD and compliance with the Rights in Early Childhood provisions of the Convention on the Rights of the Child, as preconditions for international developmental assistance, are two mechanisms that can be used. Analogous mechanisms have been used effectively in other areas of international development in the past.

Civil society groups are conceptualized as being organized at, and acting on, all levels of social organization, from local residential through global. The ability of civil society to act on behalf of children is a function of the extent of “social capital” or connectedness of citizens, and the support of political institutions in promoting expressions of civil organization. When civil society is enabled, there are many avenues through which they can engage on behalf of children. Civil society groups can initiate government, non-government organization, and community action on social determinants of ECD. They can advocate on behalf of children to assure that governments and international agencies adopt policies that positively benefit children’s well-being. Finally, civil society groups are instrumental in organizing strategies at the local level to provide families and children with effective delivery of ECD services, to improve the safety, cohesion, and efficacy of residential environments, and to increase the capacity of local and relational communities to better the lives of children. Although research on the direct effect of civil society on ECD is limited, the strong statistical association between the strength of civil society and human development in societies around the globe leaves little doubt about its importance to ECD.
Introduction

The early child period is considered to be the most important developmental phase throughout an individual’s lifespan. Healthy early child development (ecd)—physical, social–emotional, and language–cognitive—is fundamental to success and happiness not only for the duration of childhood, but throughout the life course. ecd strongly influences well-being, obesity/stunting, mental health, heart disease, literacy and numeracy skills, criminality, and economic participation throughout life—all issues that have profound implications for economic burden on countries. If the window of opportunity presented by the early years is missed, it becomes increasingly difficult, in terms of both time and resources, to create a successful life course. Governments must recognize that effective investments in the early years are a cornerstone of human development and central to the successfulness of societies. Indeed, our planet provides no examples of highly successful societies among those who have ignored development in the early years. It is therefore critical for governments, international agencies, and civil society partners to move from knowledge to action in ecd. We base this report on the assumption that every child has a basic right to a name and a nationality but we know that many children the world over are not registered at birth.

ecd is important in all countries, resource-rich and -poor alike, but special attention needs be paid to the potential benefits to the resource-poor, where a child has a four in ten chance of living in extreme poverty and 10.5 million children die before age 5. Such children are likely to suffer from poor nutrition and poor health. They are also at high risk of never attending school (UNESCO 2007). The recent Lancet series on ecd estimates that there are 553 million children under 5 in developing countries—including 155 million who are not stunted and 62 million who are stunted but are living in poverty—for a total of over 2 billion children under five years of age who are at extreme risk of impaired cognitive and social–emotional development. Most of these children—89 million—live in ten countries (India, Nigeria, China, Bangladesh, Ethiopia, Indonesia, Pakistan, Democratic Republic of Congo, Uganda, and Tanzania) that account for 219 million disadvantaged children in the developing world. Many are likely to do poorly in school and subsequently as adults will likely have low incomes, high fertility, and provide poor health care, nutrition, and stimulation to their own children, thus contributing to the intergenerational transmission of disadvantage (Grantham-McGregor et al., 2007). The loss of human potential that the above statistics represent is associated with more than “a 20% deficit in adult income and will have implications for national development” (Grantham-McGregor et al., 2007, p. 67).

The overarching message of this report to governments, international agencies, and civil society partners is this: the agenda to improve child survival and health is indivisible from the agenda to improve early child development. The agenda to improve child survival and health is indivisible from the agenda to improve early child development.

Governments must recognize that effective investments in the early years are a cornerstone of human development and central to the successfulness of societies.

The recent Lancet series on ecd estimates that there are 553 million children under 5 in developing countries—including 155 million who are not stunted and 62 million who are stunted but are living in poverty—for a total of over 2 billion children under five years of age who are at extreme risk of impaired cognitive and social–emotional development.
Introduction

Governments should adopt a strategy of investing in early child development in order to meet the Millennium Development Goals for poverty reduction, education, and health.

Economists now argue on the basis of the available evidence that investment in early childhood is the most powerful investment a country can make, with returns over the life course many times the amount of the original investment. Globally, societies—rich or poor—that invest in children and families in the early years have the most literate and numerate populations. These are also the societies that have the best health status and lowest levels of health inequality in the world. Societies with the most successful policies and programmes for ECD spend approximately 1.5%–2.0% of GDP per year on it (OECD, 2006). One study has estimated that every dollar spent to help a child reach school age while thriving can generate up to $17 in benefits to society over the following four decades (even after controlling for inflation) (Schweinhart, Barnes & Weikart, 1993; Schweinhart, 2004).

While the academic and grey literature provides compelling evidence about the importance of the early years, in practice, ECD is not at the centre of international, national, or local policies, programming and practice. Despite the strength of the evidence, adequate investments in ECD have been slow, particularly in resource-poor countries where the greatest number of vulnerable children would benefit the most.

Within the work of the Commission on Social Determinants of Health (CSDH), ECD has strong links to other social determinants of health, particularly Urban Settings, Gender, Globalization and Health Systems. Areas of common concern with these determinants are made clear, though implicit, throughout this document. Moreover, we argue that Child Survival, Child Health, Education for All, and Child Rights agendas are indivisible from ECD.

Again, taking a developmental perspective on the early years provides a framework of understanding that incorporates issues of survival and health as well as education and rights.

SCOPE OF WORK

This work includes evidence related to infants and children, from prenatal development through to eight years of age, specifically considering how social determinants influence health across the life course. It is of relevance to children on a global scale. We discuss the limitations to the application of these ideas where appropriate.

PURPOSE

The purpose of this document is to synthesize knowledge to inform the CSDH about opportunities to improve action on a global scale in the area of ECD. The evidence assembled here focuses on priority associations between social determinants of health and health inequities across different country contexts. It comments on the extent to which the social determinants of ECD can be acted upon, is intended to stimulate societal debate on the opportunities for acting on social determinants of health and to inform the application and evaluation of policy proposals and programmes in the area of ECD—nationally, across regions and globally. The areas of focus for each of the Commission’s Knowledge Networks—Globalization, Social Exclusion, Health Systems, Gender, Urban Settings, Employment Conditions, Priority Public Health Conditions and Evidence & Measurement—are critical to understanding the social determination of ECD, and as such are integral to this review.

CONCEPTUAL FRAMEWORK

The Total Environment Assessment Model of Early Child Development (TEAM-ECD) has been developed for the CSDH as a means of framing the types of environments (and therefore experiences) that are integral to healthy ECD, and linking these to the biological processes with which they interact to shape children’s outcomes (Siddiqi, Irwin & Hertzman, 2007). The TEAM-ECD model builds on a diverse literature, including previously described frameworks that have addressed ECD from a social environmental perspective. These sources include Urie Bronfenbrenner’s Bioecological Model (1986); developmental psychology perspectives on ECD (Brooks-Gunn, Duncan & Maritano, 1997); notions of “biological embedding” (Hertzman 1999); frameworks of understanding regarding social epidemiology and social determinants of health (Dahlgren & Whitehead, 1991; Emmons, 2003); research regarding social relations in human society (Furman, 2000; Weber, 1946); a vast literature in the political economy domain (for a review of this literature, see Siddiqi, Irwin & Hertzman, 2007); and the World Health Organization (WHO) Framework on Social Determinants of Health (Solari & Irwin, 2005). Because the WHO Equity Team framework considers ECD as a determinant of health, it becomes crucial here to address the factors influencing ECD itself. By expanding the notion of environmental spheres of influence, adding a temporal component, and placing children’s well-being at its centre, TEAM-ECD offers the strongest means of understanding (and therefore acting upon) social determinants of ECD.

SPHERES OF INFLUENCE ON EARLY CHILD DEVELOPMENT

In this schematic (see figure), a variety of interacting and interdependent spheres of influence are instrumental for development in early childhood. They include the individual, family, and dwelling; environmental and relational communities; ECD programmes and services; and regional, national and global environments. In each sphere of influence, social, economic, cultural and gender factors affect its nurturant qualities.

Methods

The process of synthesizing the available evidence raised the question of what counts as evidence. We paid attention to the quality of the source, the context of the research, the nuances of particular programmes and populations served, and the ecological factors associated with the studies. Accordingly, our evidentiary base is derived from three primary sources:

1. peer-reviewed scientific literature,
2. reports from governments, international agencies, and civil society groups and
3. international experts in ECD (including the CGI Knowledge Network for ECD that is representative in both international and inter-sectoral terms).

This Final Report is a summary of a broader comprehensive evidence document entitled, like the model, TEAM-ECD (Siddqi, Irwin & Hertzman, 2007), so when in-depth information is at issue, we refer back to TEAM-ECD. Although there is a wealth of literature related to ECD, only a limited number of studies focus upon ECD in resource-poor countries. In addition, although we believe that qualitative research findings contribute a unique and important source of information to a review such as this, the availability of studies employing qualitative methods was limited. There is also a heavy weighting of evidence in the literature for “at risk” or special populations, but these studies are also concentrated in resource-rich nations.

We took a broad view of what literature was relevant to ECD (see Appendix A), investigating databases from multiple disciplines, including medicine, development, psychology, sociology, nursing, population health, economics and anthropology. For each, evidence that pertained to any aspect of children’s well-being was included. In addition, papers addressing the interconnectivity of family, residential, relational and broader societal contexts were reviewed, even when these papers did not make direct reference to effects on children. Whenever possible we used “causal evidence” in the scientific sense and complemented it with practical and personal experiences drawn from a wide variety of sources. While we have used the highest quality research evidence available, we are also aware that not all high-quality research is of practical significance or equally applicable in all global contexts. This multi-source, multi-method approach helped to ensure that the conclusions and recommendations of this report are consistent with the perspectives of a diverse array of stakeholders, and are broadly applicable to societies throughout the world.

We acknowledge both the limitations posed by many of these studies being focused in resource-rich nations, and the many challenges that limit the extent to which experiences, programmes and research findings from one global context can be applied to others.

Results: TEAM-ECD Spheres of Influence

The Individual Child

The earliest years of life are characterized by the most important development that occurs in a human lifespan. There are several bases for the bold and unequivocal nature of this statement. The early years are marked by the most rapid development, particularly of the central nervous system. The “sensitive periods” for the development of the brain almost exclusively occur during this time. During these early years, the experiences (e.g., good quality nutrition) and the environmental exposures (e.g., attachment to a caregiver) that a child receives will be instrumental in the successful development of early brain function. Not only will the child be shaped by these experiences psychologically, but the child will also shape these experiences. The development that occurs in the early years provides the essential building blocks for a lifetime of success in many domains of life, including economic, social and physical well-being.

Biological Embedding

The interaction that occurs between individual characteristics (genetic and physiological) and experiences and exposures drawn from the environment are basic to the development of the child. The human brain, in particular, is the “master organ” of development. Early in life, genetically programmed sensitive periods occur in the brain, during which time the developing child is disproportionately sensitive to the influences of the external environment (Barker, 1992; Bronfenbrenner, 1986; Wadsworth, 1997). The interplay of the developing brain with the environment is the driving force of development; its legacy is a unique configuration of synapses in the brain that influences and is influenced by cognitive, social and emotional functions thereafter. The process of early experience becoming solidified and influencing health and development over the long-term is known as biological embedding (Hertzman, 1999).

Nutrition

Children’s optimal growth and development requires adequate nutrition, and receiving adequate nutrition is a fundamental right of children (see General Comment #7 on the Convention on the Rights of the Child [CRC] [United Nations Office of the High Commission for Human Rights, 1990]) and begins in utero with adequately nourished mothers. During the first months of life, breastfeeding plays a critical role in providing children with the necessary nutrients. In fact, exclusive breastfeeding is thought to reduce the chances of early post-natal stunting (Smith et al., 2010). Breastfeeding carries with it the dual role of adequate nutrition and healthy infant development through stimulation and attachment as part of the breastfeeding process. Despite what the evidence—both scientific and traditional—tells us about adequate nutrition for infants and children, there are approximately 150 million children under the age of five years in the developing world alone who suffer from malnourishment. Children who are malnourished are more likely to suffer the consequences of poor physical and mental development; have poorer school performance (Pelto, Dickin & Engle, 1999; Powell et al., 1998; Winicki & Jemison, 2003); be susceptible to the effects of infection; have more severe diarrhoeal episodes; have a higher risk of pneumonia; have lower functioning immune systems; and often have low levels of iodine, iron, protein and...
Nutritional deficiencies at all stages of growth have long-term damaging effects on the intellectual and psychological development of children. Malnutrition is also implicated in more than half of all child deaths worldwide. In addition to its devastating impact on child mortality, nutritional deficiencies especially for children under three years old have long-term damaging effects on the intellectual and psychological development of children: unacceptable loss of human potential (Granham-McGregor et al., 2007). Malnutrition is therefore one of the most important factors in poor development and loss of development potential for children. We know that stunting as a result of chronic malnutrition is shaped by a complex combination of environmental, social and economic factors, which begin in utero and affect both physical growth and mental development. Here is a prime example of where child survival, food security, ECD, education and gender equity agendas converge. It is essential to reduce malnutrition globally, especially in to 1 year olds, but this requires systematic action at the local level in the areas of maternal health (including adequate nutrition) and health care; food security, with adequate micronutrient intake; safe water; access to education for all; and protection from illness such as provided by immunization programmes. While attention to these factors is important, it is equally important to ensure the presence of a systematic, community-based follow-up and support for malnourished children and their families—especially the most vulnerable children.

 RELATIONSHIPS

Although adequate nutrition is essential for development, the quality of relationships is equally important for children’s development. Existing literature leads us to consider children as social actors (Boydlen & Levison, 2000; Irwin, 2006; Irwin et al., 2007; Irwin & Johnson, 2005; Mayall, 1996), who are not only shaped by their environment but, in turn, shape it as well. A child’s individual development is transactional, reciprocal and mutually constituted. Young children develop best in warm, responsive environments that protect them from inappropriate disapproval and punishment, environments in which there are opportunities to explore their world, to play, and to learn how to speak and listen to others (Ramey & Ramey, 1998). Notwithstanding the complexity of ECD, the many factors that influence ECD come down to these simple attributes of the child’s day-to-day experience. Improving the quality of children’s day-to-day experience through relationships needs to be a primary goal of all initiatives regarding of parenting, childcare, and monitoring rights in early childhood under the CRC.

THE SCIENCE OF PLAY

The central role of play in children’s development is not always appreciated. Play processes influence synaptic formation and are linked to secure attachment with caregivers and relationships with other children. Play provides an important socializing function, beyond the merits of being physically active, in which children learn about and negotiate identity and the social subtleties of relationships (James, 1993). Play may vary according to individual children’s temperaments, gender, culture or their families’ parenting and caregiving practices, but the impact of play on developmental processes is universal across cultures (Birmstein et al., 1999). Play can be structured or unstructured; it can be done alone, with a caregiver or in a group; it evolves over time; it requires, at a minimum, a safe environment and developmentally appropriate resources. Stimulation (e.g., mothers and children playing with homemade toys with a focus on guided learning and exploration) has an independent effect on perceptual motor development outcomes among stunted children, over and above nutritional supplementation (Granham-McGregor et al., 1997). McArdie suggests that “play is marginal to the plans of governments and local authorities” (2003, p.512) and not viewed as a “serious” activity. Potentially, one of the most efficient strategies for improving ECD is to find ways to convince parents and caregivers of the importance of play and the ways they can promote it.

KEY MESSAGES: THE INDIVIDUAL CHILD

1. Health, nutrition, and well-being of the mother are significant for the child’s development.
2. These broad domains of development—physical, social–emotional and language–cognitive—are interconnected and equally important.
3. Children shape their environments as well as being shaped by them.
4. Social determinants shape brain and biological development through their influence on the qualities of stimulation, support, and nurturance available to the child.
5. Play is critical for a child’s overall development.

The Family

The family is the primary influence on a child’s development (UNICEF, 2007) (“Family” is defined here as any group of people who dwell together, eat together, and participate in other daily home-based activities together). The new CRC General Comment 17 on Early Childhood restates the CRC’s position on family as, “the fundamental group” and the “natural environment” for growth and well-being but recognises that the concept of family extends well beyond the “nuclear” model. Parents and caregivers are identified as principal actors in the construction of identity and the development of skills, knowledge and behaviours, and as decision-makers in the realisation of the young child’s rights.

Family members provide most environmental stimuli for children, and families largely control a child’s contact with the distal environment (Richer, 2004). The most salient features of the family environment are its social and economic resources. Social resources include parenting skills and education, cultural practices and approaches, intra-familial relations, and the health status of family members. Economic resources include wealth, occupational status and dwelling conditions. Social and economic resources for children are highly intertwined, yet imply different strategies for intervention.

RELATIONSHIPS

A strong body of research demonstrates the significance of primary caregivers (and by extension, families) on children’s long-term development (Shonkoff & Phillips, 2000). Those factors that facilitate healthy social bonds and the character of caregiving practices that matter most for children are now well understood. A key requisite for healthy ECD is secure attachment to a trusted caregiver with consistent caring, support and affection early in life (Bowlby, 1969–76). Securely attached infants and toddlers are more resilient and are better equipped to deal with stress. Securely attached children are also more likely to have healthy relationships, better educational outcomes, and fewer emotional problems in adulthood. Research suggests that nurturing early childhood caregiving experiences can have a lasting impact on later well-being (Belsky, 1999; Chilman & Scott, 1995; Widom, 1989).

While in this section we focus on caregivers and attachment as “family” broadly defined, we want to emphasize the importance of connectedness to kin and relational communities for support and stimulation.
their emotional and physical security as a base from which to explore their environment. Successful attempts at exploration increase the child’s self-confidence and encourage more exploration. Thus, the child begins to learn about and master his or her environment and to gain in both competence and self-confidence. All families need some support to learn how to develop and be sensitive and responsive in their childcare practices. There are, however, both biological and environmental factors that can negatively impact on attachment. These include low birth weight, malnutrition and infections, poverty and its associations, conflict and domestic violence, and mental health problems such as maternal depression. In these instances, external support for families is particularly important.

Socioeconomic Status

So consistent is the association between socioeconomic status (SES) and a variety of development and health outcomes throughout the lifespan, that it has been termed a “gradient effect.” The gradient effect of family resources on ECD is the most powerful explanation for differences in children’s well-being within societies, and these resources profoundly affect all other aspects of the family environment. The gradient effect of family resources on ECD is the most powerful explanation for differences in children’s well-being within societies, and these resources profoundly affect all other aspects of the family environment.

Early Childhood Development: A Powerful Equalizer

Spheres of Influence: The Family

The Family

Fathers

The role of fathers as part of the family-level sphere should not be underestimated, and is often regrettable marginalized. The United Nations Commission on the Status of Women (“encourages” men to participate fully in all actions towards gender equality and “[urges] the establishment of the principle of shared power and responsibility between women and men at home, in the community, in the workplace, and in the wider national and international communities” (United Nations Office of the High Commission for Human Rights (UNCSW), 2004, p. 1). Certainly, this includes the role of fathers in nurturing their families. Men who affect the well-being of children and families is now firmly emphasized in policy frameworks as a strategic requirement for all children’s services (Fathers Direct, 2006).

Gender

Inequities within families may be significant from the standpoint of the social determinants of health, especially with respect to gender. “Women’s access to power at the household level has the most direct impact on families and children … [through lack of control over] allocation of resources for food, health care, schooling and other family necessities” (UNICEF, 2007, p. 13). As a result, female children are more likely to receive less food, and to be denied essential health support for families is particularly important.

Socioeconomic Status

So consistent is the association between socioeconomic status (SES) and a variety of development and health outcomes throughout the lifespan, that it has been termed a “gradient effect.” The gradient effect of family resources on ECD is the most powerful explanation for differences in children’s well-being within societies, and these resources profoundly affect all other aspects of the family environment.
Gender equity at the family level contributes to reducing the intergenerational transmission of poverty through improved development, access to education, and proper feeding.

services and education. Household chores and caregiving keep adult women out of the paid labour force and girls out of school. Moreover, when mothers do work, female children are more likely to be kept home from school to care for other siblings, especially when there is no option for substitute caregivers such as childcare. Also according to the recent UNICEF report, nearly 1 in every 5 girls who enrolls in primary school in developing countries does not complete a primary education. Missing out on a primary education deprives a girl of the opportunity to develop to her full potential. Research has shown that educated women are less likely to die in childbirth. ... are more likely to send their children to school. ... It is clear that women’s roles (decision-making power) within the family, as well as their educational levels, play an important part in promoting eCD. Women’s education not only contributes to lower mortality rates but also long-term education for girls. Gender equity at the family level contributes to reducing the intergenerational transmission of poverty through improved development, access to education, and proper feeding (UNICEF, 2007).

Family Dwelling

The family dwelling also contributes to (or detracts from) nurture for children. Physical and mental health are linked to housing conditions such as overcrowding, indoor air pollution, and dampness and cold (Dunn & Hayes, 2000). Conditions in slums and shanty-towns can present further risks for children. Studies of homeless families and children find much higher rates of physical and mental illness and worse developmental outcomes among this population (Dunn & Hayes, 2000). These conditions exacerbate the other socioeconomic challenges that many families face on a daily basis.

Family Support

Families need to be able to access the resources that enable them to make choices and decisions in the best interests of their children, including services such as parenting and caregiver support (Richter, 2004), quality childcare (Goelman, 2003; Lamb, 1998; NICHD, 1996; 2002; Vandell, & White, 2000), and primary health care and education. Globally, one particular area where families require social protection is in resolving the demands of work and home life. Heymann’s (2006) research on children and families in resource-poor countries demonstrates the importance of access to quality childcare for families in the world over (see Appendix D). Her research demonstrates that millions of children worldwide are being left home alone, left in informal childcare (often in the care of other children), or being brought to work and exposed to unsafe working conditions. Public provision of quality, affordable childcare is part of the solution to this problem.

Resilience

Many families that face daily challenges because of their socioeconomic disadvantages are nevertheless able to create the essential nurturing environments for their children. Resilience refers to the capacity of a child to thrive, despite growing up facing adversity. Berman’s research on children in vulnerable circumstances (1996, p. 5) provides the most important social relationships for enhancing children’s resilience (Grotberg, 1995). Children all over the world face situations such as witnessing and experiencing violence in their families and the broader community, bullying, disability, divorce, and witnessing or experiencing the effects of alcohol and substance abuse in their families, while others confront catastrophic events or day-to-day atrocities such as war, poverty, disease, famine, floods, HIV/AIDS, and forced labour. How a child emerges from these situations depends upon multiple factors at the individual, family, community, and broader societal levels (Bartley, 2006; Grotberg, 1995). Studies of the experiences of children exposed to war and children of battered women demonstrate that the family can provide a buffer against extreme circumstances (Berman, 1996). Berman’s research on children’s resilience and the “family as a fundamental source of nurturing for a child” (1996, p. 5). The family is a fundamental source of nurturing for a child. Socioeconomic gradients in developmental outcomes reflect difficulties families with few resources face in providing nurturing environments for their children. The ‘gradient effect’ occurs for almost all outcomes in almost all places speaks to the critical nature of socioeconomic resources.

Families require access to a range of supports and programs for their children, but also for themselves. Within families, gender-based bias may create inequities in the nurturant conditions afforded to girls compared with boys. Giving greater power in decision-making to mothers can alleviate some of this inequity.

Safety nets, such as social protection policies, access to appropriate services, and sufficient income, to enhance their ability to bolster children’s resilience.

and other studies point to the importance of enhancing the family’s capacity to support young children in times of stress and adversity (Pinheiro, 2006). Families require proper safety nets, such as social protection policies, access to appropriate services, and sufficient income, to enhance their ability to bolster children’s resilience regardless of the daily challenges the family faces.

Resilience can be enhanced through the relationships that families, caregivers, and children establish with others in their locality or relational communities (e.g., religion-based communities), as well as through eCD, health, nutrition, and other services that are provided by governmental and non-governmental organizations (NGOs), and through larger policies that facilitate educational attainment, income transfers, health care, and access to safe housing. Institutional features of society that strengthen the “connectedness” of citizens in positive ways will enhance resilience in children and families (e.g., Positive Deviance [UNICEF, 2005]). Accordingly, governments, international agencies, and civil society groups should use the criterion of “connecting children with adult mentors” to judge programme and policy proposals.

KEY MESSAGES: THE FAMILY

1. The family is a fundamental source of nurturing for a child.
2. Socioeconomic gradients in developmental outcomes reflect difficulties families with few resources face in providing nurturing environments for their children.
3. The ‘gradient effect’ occurs for almost all outcomes in almost all places speaks to the critical nature of socioeconomic resources.
4. Families require access to a range of supports and programs for their children, but also for themselves.
5. Within families, gender-based bias may create inequities in the nurturant conditions afforded to girls compared with boys. Giving greater power in decision-making to mothers can alleviate some of this inequity.
Residential and Relational Community

The child and family environment is shaped both by the residential community (where the child and family live) and the relational community (based on social ties among networks of people with a shared identity).

Residential Communities

The core features of residential communities that have been identified as being important for ECD include the socioeconomic, physical, and service environments (Kawachi & Berkman, 2003). The socioeconomic environment of residential communities can be defined according to average or median income level, the percentage of residents with a high school diploma, or the percentage of employed or unemployed individuals in the community (Leventhal & Brooks-Gunn, 2000). High levels of socioeconomic status are generally associated with better school readiness and school achievement in younger children (including verbal and reading skills). Although socioeconomic inequalities between residential communities are often associated with inequalities in children’s development, there are important caveats. Children from low SES families living in economically mixed neighbourhoods generally do better in their development than low SES children living in poor neighbourhoods (Kohen et al., 2003). Adopting policies to create economically mixed residential neighbourhoods does not cost government any benefits for young children.

Physical and Service Characteristics

There is a clear inverse association between the socioeconomic status of a community and the extent to which its residents will be exposed to toxic or otherwise hazardous exposures such as wastes, air pollutants, poor water quality, excessive noise, residential crowding, poor housing quality, and the like (Evans, 2002). The physical spaces accessible to children create both the opportunities and the constraints for play-based learning and exploration, which are critical for motor, social/emotional, and cognitive development (Irwin, 2006; James, 1993). Similarly, the availability of high quality services will vary according to the socioeconomic circumstances of communities, including institutions and facilities for learning and recreation, childcare, medical facilities, access to transportation, food markets, and opportunities for employment (Leventhal & Brooks-Gunn, 2000). In both resource-rich and resource-poor countries, local access to these essential services for children should be used as a criterion for urban development.

Slums and Shantytowns

Globally, an increasing number of children are growing up in slums or shanty-towns, but children’s cognitive and socio-behavioural outcomes in these contexts have not been explored in a systematic way. The extent to which government policies support legal legitimacy, basic housing, nutrition, schooling, health, and other basic public services is crucial, particularly with the rapid rate of urbanization occurring around the world. There are organizational models for mitigating the adverse effects of slum and shanty-town conditions (Dayal, 2001).

In both resource-rich and resource-poor countries, local access to essential services for children should be used as a criterion for urban development.

Relational Communities

The relational community is a primary influence on how children and families identify themselves and others, and how outsiders identify children. Therefore, it is a primary source of social inclusion and exclusion, sense of self and self-worth, self-esteem, and gender socialization. The extent to which adults and children in communities are linked to one another, whether there is reciprocated exchange (of information, in-kind services, and other forms of support), and whether there is informal social control and mutual support, are determined at this level. These characteristics, known variously as social capital or collective efficacy, have been shown to be nurturant for children and their families, both in the context of urban neighbourhoods in resource-rich nations (Samson, Morenoff & Earls, 1999) and in the village context in resource-poor nations (Carter & Maluccio, 2003). Essentially, child outcomes relate to the social ties between community residents that facilitate the collective monitoring of children related to shared community norms and practices, as well as positive role modelling (Bourdieu, 1984; Coleman, 1988, 1990; Jemus-R Termin, 1990; Putnam, 2000). Relational communities are often a main mechanism through which information regarding child-rearing practices, and child health and development are transmitted. Traditions regarding child rearing are passed down through generations, not only within families but also throughout broader socially bonded groups.

Spheres of Influence: Residential and Relational

KEY MESSAGES: RESIDENTIAL AND RELATIONAL COMMUNITY

1. The integrity and accessibility of physical space in which children can explore and play is critical for all three domains of ECD.
2. The physical, socioeconomic, and service aspects of residential communities all strongly influence ECD.
3. Relational communities are a primary source through which families derive values, norms, and social support.
4. Bonding within relational communities may result in social exclusion (even conflict and discrimination) between them.
5. Gender norms and roles are often rooted in the social beliefs of relational communities, thus addressing gender equity at this level is essential.
**ECO Programme and Services**

Quality ECD programmes and services are those that nurture all aspects of a child’s development—physical, social, emotional, language, and cognitive. Governments need to integrate quality ECD programmes and services into social protection policies⁴ to ameliorate the effects of growing up in poverty for millions of children worldwide and to meet the Millennium Development Goals. The evidence is disturbing: 40% of children in resource-poor nations live in extreme poverty; 10.5 million children die before they are 5 years old; many children never attend school; 38% of children in resource-poor countries are stunted (Grantham-McGregor et al., 2007). Evidence shows that conditions in resource-poor countries that foster poverty, illness, lack of access to schooling, and malnutrition lead to an intergenerational transmission of poverty affecting the productivity of future adults and putting an increased burden of cost on the economic resources of a country. In resource-rich countries, the conditions are not as dramatic and the implications for human development are not as dire, but the differences are really just a matter of degree. Across the resource-rich world, developmental vulnerability rises as one goes down the socioeconomic spectrum, such that, in most OECD countries, 25% or more of children reach adulthood without the basic literacy and numeracy skills required to cope in the modern world (Williams, 2003). Thus, ECD is an issue for all societies, not just the resource-poor.

Kamerman and Gabel’s global overview of social protection policies found that in OECD countries, policies that had a positive influence on outcomes for children included “increasing children’s access to reasonable quality early childhood care and education” (2006, p. 11). They also found that in countries where resources were limited (and policy data is also sparse) priorities must be set such that the most vulnerable are targeted, while universal coverage should remain the longer term goal.

**ECONOMIC ARGUMENTS**

Economists now assert on the basis of the available evidence that investment in early childhood is the most powerful investment a country can make, with returns over the life course many times the size of the original investment. ECD programmes foster and promote the quality of human capital: that is, individuals’ competencies and skills for participating in society and the workforce (Knudsen, et al., 2006). The competencies obtained and skills fostered through ECD programmes are not limited to cognitive gains, but also include physical, social, and emotional gains, all of which are determinants of health over the life course (Carneiro & Heckman, 2003). Much of the burden of disease worldwide (e.g., cardiovascular disease, obesity, HIV/ AIDS, depression) begins in early childhood (Marmot & Wadsworth, 1997). Accordingly, ECD programmes—which incorporate and link health-promoting measures (e.g., good nutrition, immunization) with nurture, participation, care, stimulation, and protection—offer the prospect of sustained improvements in physical, social, emotional, language, and cognitive development, while simultaneously reducing the immediate and future burden of disease, especially for those who are most vulnerable and disadvantaged.

According to the recent UNICEF Global Monitoring Report, in every country, 115 children from the poorest communities who are least likely to have access to ECD programmes—“those most exposed to malnutrition and preventable diseases”—yet who would also benefit the most. (UNESCO, 2007)

and skills fostered through ECD programmes are not limited to cognitive gains, but also include physical, social, and emotional gains, all of which are determinants of health over the life course (Carneiro & Heckman, 2003). Much of the burden of disease worldwide (e.g., cardiovascular disease, obesity, HIV/AIDS, depression) begins in early childhood (Marmot & Wadsworth, 1997). Accordingly, ECD programmes—which incorporate and link health-promoting measures (e.g., good nutrition, immunization) with nurture, participation, care, stimulation, and protection—offer the prospect of sustained improvements in physical, social, emotional, language, and cognitive development, while simultaneously reducing the immediate and future burden of disease, especially for those who are most vulnerable and disadvantaged.

According to the recent UNICEF Global Monitoring Report, in every country, 115 children from the poorest communities who are least likely to have access to ECD programmes—“those most exposed to malnutrition and preventable diseases”—yet who would also benefit the most (2007, p. 19).

Engle et al. remind us “to achieve the Millennium Development Goals of reducing poverty and ensuring primary school completion for girls and boys, governments and civil society should consider expanding high quality, cost-effective ECD programmes” (2007, p. 239). Early interventions can alter the lifetime trajectories of children who are born poor or are deprived of the opportunities for growth and development available to those more fortunate. ECD programmes and services (e.g., childcare for working parents, preschool, access to primary school) have high rates of return, and are an effective route to reduce poverty, foster health, productivity, and well-being.

If governments in both resource-rich and resource-poor societies were to act while children were young, by implementing quality ECD programmes and services as part of their broader social protection policies, they would each have a reasonable expectation that these investments would pay for themselves many times over (Schweinhart, et al., 1993; Schweinhart, 2004). In resource-rich countries where the issue has been studied directly, savings come from reduced remedial education and criminal justice costs (Schweinhart, et al., 1993; Schweinhart, 2004). Economic gains come from improved access of mothers to the labour force (Cleveland & Krushinsky, 1998) and increased economic activity in adulthood among those whose development trajectories were improved through intervention (Schweinhart, 2004—all follow-up to age 27). The economic benefits of ECD intervention over the long term have not been directly studied in resource-poor countries; however, a rather robust literature suggests economic growth in resource-poor nations accrues to a variety of outcomes that stem from investments in human capital more generally, such as increased school enrollment and improved literacy rates (Komer, 1986; Ravallion and Chen, 1997; Sen, 1999; Baldacci, Clemens, Gupta and Cui, 2004).

The scale of potential economic gain for resource-poor societies in adopting child development as a cornerstone to their development strategies can be measured not just in cost-benefit terms at the micro level, but in multiples of economic scale.

---

⁴ Governments have an obligation to provide social protection affecting children which includes 1) social insurance/economic support: conditional/unconditional cash transfers, child care grants, social pensions, rations, benefits, food and food vouchers; and 2) social services for children and their families including protective (and preventive) services such as foster care, adoption, residential treatment, family and community support services for children with special needs, and in some cases, early childhood care (Kamerman & Gabel, 2016).

⁵ Human capital refers to the accumulated pool of human resources that are transferable into economic productivity for a society.
Beyond the aspects of quality programmes, a set of principles has been demonstrated to sustain ECD programmes and services worldwide. This includes cultural sensitivity and awareness; community ownership; a common purpose and consensus about outcomes related to the needs of the community; partnerships among community, providers, parents, and caregivers; enhancing community capacity through active involvement of families and other stakeholders; and an appropriate management plan (which includes users) that facilitates the monitoring of quality and the assessment of programme effectiveness (Kagan & Britto, 2005). With respect to ECD programmes and services, a number of studies have shown these quality principles to enhance outcomes for young children (e.g., Anderson et al., 2003). Consultative Group on Early Childhood Development & Bernard van Leer Foundation (2005). Linking ECD programmes and services with health care systems will improve child survival rates.

HEALTH CARE SYSTEMS

Health care systems (HCSs) are in a unique position to contribute to ECD at a population level, given that HCSs are already concerned with the health of individuals and communities, employ trained professionals, provide facilities and services, and are a primary contact for child-bearing mothers. In many instances, health care providers are the only health professionals whom families come into contact with in the early years of the child’s life; they reach the majority of children in a community. When the HCS is used as a linkage point, health care professionals can be highly effective in promoting ECD.

The critical interaction of effective ECD and child survival agendas happens in HCSs. While this report has included devastating statistics about millions of children dying throughout the world—many from preventable deaths, national health systems can make a significant difference by ensuring that ECD is integrated into their work. Early identification and intervention can prevent the loss of children’s lives and improve their long-term outcomes. By working together, health care providers and community organizations can create a supportive environment for children and their families, laying the foundation for a healthy start in life.
able causes—here we suggest that linking ECD programmes and services with HCSS will improve child survival rates. The example of Kangaroo Care from Bogota, Colombia, is instructive here. Kangaroo Care is based on mothers, fathers and caregivers providing skin-to-skin contact for low birth-weight infants as part of early stimulation and warmth, which has been shown to improve survival rates of the most vulnerable infants. Through skin-to-skin contact for warmth, infants gain the early stimulation that matters for their survival; costs of this intervention are minimal, but benefits are immeasurable.

While the case of Kangaroo Care is a unique hands-on intervention, developed in hospitals and carried out within and beyond the walls of institutions, health care providers can facilitate ECD in various other ways as well. HCSS can serve as a platform for information and support to parents around ECD; they can integrate ECD into existing programmes such as IMCI (Integrated Management of Childhood Illness) / Care for Development, ACED (Accelerated Child Survival and Development), BPHI (Baby Friendly Hospital Initiative) (UNICEF, 2007), and nutrition/growth monitoring and promotion that exist in most countries; they can then link children and families to existing community-based ECD services. Examples of this process include health or community development programmes that have added an early stimulation and care component, and TCD programmes that have been coupled with other health services such as a women’s health programme or a reproductive health programme. They are an important point of contact that can extend ECD programming to children and families who would otherwise have no access, and can often do so for relatively small marginal costs. Because of the opportunity that HCSS provide simple interventions that have a far reach could be added. For example, if culturally and developmentally suitable lowcost books for early child development were available, health care professionals could provide families with books and encourage reading and stimulation. A notable exception to using the HCSS as a point of contact is in the case of remote rural areas or urban slums of resource-poor countries, where HCSS cater to populations who are either too poor to access health services, or the services are inaccessible or too weak. In these situations, most community-based interventions for women, children, and families are delivered by NGOs and voluntary organizations (e.g., SEWA, programmes delivered by Save, and the BVLP, Aga Khan, and Soros Foundations’ community development projects). Further details can be found about Equal Access: Using Communications to Reach Parents and Communities on Early Child Development in Nepal and Village-Based ECD Curriculum Development in Lao PDR in Appendix B.

Local, regional, and national governments, with the support of international agencies and civil society partners, must be the key players in developing, promoting, and funding a basket of ECD programmes and services that conform to the principles articulated here.

Key Messages: ECD Programmes and Services

1. Public investment in early childhood programmes and services is extremely powerful, with far greater returns to society occurring in many areas (education and beyond) and throughout the life course.
2. The ultimate goal of every society should be universal access to quality services and programmes that are built on existing service infrastructure (e.g. health care systems).
3. There are multiple entry points for ECD services and programmes, including health care systems, community-based childcare, and preschool education.
4. Health care systems (HCS) are a uniquely powerful position to contribute to ECD, since they are often the first system-of-contact for children and mothers.
5. HCS can ensure that development programmes address ECD in a comprehensive manner, combining health and nutrition with early learning; addressing the needs of children and of families.
6. Current effective strategies through HCS should be widely implemented in resource-poor countries.
7. Those responsible for ECD programmes and services must develop partnerships with families and tailor services to the needs of those they serve.
8. Programmes and services should be built upon understandings of quality and equity, and should be monitored in these regards.
9. Governments have a central role to play to ensure that ECD programmes and services are fully integrated into social protection policies.

Regional and National

The influence of the regional and national environments is fundamental in determining the extent of services and resources that are available to communities and to families. Many interrelated aspects of regional environments may be significant for ECD, including the physical (e.g., degree of urbanization, the health status of the population), the social, the political, and the economic environments. These aspects of the regional environment affect ECD through their influence on the family, community, and ECD services.

Most of the research performed thus far on regional characteristics in relation to human welfare concerns the impact of the socio-political environment. For instance, a rich literature (primarily derived from the United States) demonstrates an association between state-level income inequality (i.e., distribution of income) and a variety of health outcomes. The research suggests that, above and beyond the wealth of a region (in this case, the state), the greater the inequality in the distribution of income between households, the worse the health and related outcomes of the population, including adult mortality, infant mortality, low birth weight, malignant neoplasms, coronary heart disease, expenditure on medical care, homicide, and violent crime (Kaplan et al., 1996; Kennedy, Kawachi & Prothrow-Stith, 1996; Spencer, 2004). The extent of income inequality, in turn, is determined by decisions made partially at the regional level regarding wage rates, income tax, transfers, social expenditures, and other mechanisms of distribution and redistribution (Zuberi, 2001).

We know that in low- and middle-income countries, inequalities in child health outcomes—for example under-five mortality rates—vary according to geography, such as between rural and urban areas and between provinces. In regions where this is the case, the inequalities are often due to unequal allocation of resources (Houweling, Kunst, et al., 2005). Regional inequalities in ECD can also be seen in resource-rich countries, as is the case for the province of British Columbia, Canada (Kershaw, Irwin, Trafford & Hertzman, 2006). The map in
Figure 2 demonstrates a three-fold difference in rates of vulnerability (14.0 -21.3%) for children reaching school age (5 years) according to the Early Development Instrument (see Appendix C). The pie charts layered on top of the regional areas describe the social and economic characteristics of the given region. The national environment serves as a powerful influence on ecd. The basis for this statement comes in part from direct evidence on national-level factors and in part from an inescapable logical extension of the profound impact of socioeconomic factors at the family and neighborhood levels on children’s well-being. In other words, if socioeconomic conditions matter, then so too do the societal factors that create the conditions themselves (Siddiqi & Hertzman, in press). These conditions are largely a function of the institutional and structural aspects of the nation. The most salient feature of the national environment is its capacity to affect multiple environments (and thus determinants) of children’s well-being through policies and laws. Cross-national studies have found an association between the dispersion of income at the national level and a variety of population health indicators, including life expectancy and infant mortality (Rogers, 1979, Flegg, 1983). In fact, the effect of income inequality on infant mortality withstands the effects of other powerful predictors of mortality during the first year of life, including doctors per capita, nurses per capita, urbanization, female literacy, and reproductive rates (Waldman, 1992).

Socioeconomic conditions matter, so do the societal factors that create the conditions themselves.

To date, the most comprehensive review of social policies in relation to inequities in child welfare across countries examines the impact of policy on child (i.e., family) poverty among the OECD nations (Kamerman et al., 2003). Kamerman’s review identified five primary policy domains of significance:

1. income transfers (cash and tax benefits),
2. employment policies,
3. parental leave and other policies to support maternal employment,
4. early childhood education and care services, and
5. prevention and other interventions related to teen pregnancy and birth.

Data from the Luxembourg Income Study has demonstrated that, based on market income (i.e., prior to taxes and transfers), at 3%, poverty rates\(^2\) in the United States are up to 5-6% lower than in several OECD nations.

![Figure 2: Early Development Instrument (EDI) Vulnerability Map](image)

**Notes:**
- Data from the Luxembourg Income Study has demonstrated that, based on market income (i.e., prior to taxes and transfers), at 3%, poverty rates\(^2\) in the United States are up to 5-6% lower than in several OECD nations.
- \(^2\) Poverty was measured as relatives living on less than 50% of median income and 50% of median income.

**Figure 2: Early Development Instrument (EDI) Vulnerability Map**

**Vulnerable on One or More Scales**
- Percentage of children vulnerable
- Low: 14.0 - 21.3%
- 21.3 - 24.7%
- 24.8 - 27.0%
- 27.1 - 31.1%
- High: 31.1 - 45.9%

**Socioeconomic Status**
- X Aboriginal
- X Mixed, Management
- X First Generation Canadian
- Most Advanced
- Most Challenged

**Figure 2:** The national environment serves as a powerful influence on ecd. The basis for this statement comes in part from direct evidence on national-level factors and in part from an inescapable logical extension of the profound impact of socioeconomic factors at the family and neighborhood levels on children’s well-being. In other words, if socioeconomic conditions matter, then so too do the societal factors that create the conditions themselves. The research to understand how some low SES communities “buck the trend” and produce good ecd outcomes is, itself, in its infancy. We are confident that when the characteristics of these “resilient communities” are better understood, they will provide useful lessons for communities around the globe. Figure 2 also demonstrates what a powerful tool the mapping of ecd by locality and geographic region can be for the purposes of public discussion and policy-making. In regions with high levels of inequality it has been shown that poverty impacts performance in the early school years.

At the sub-national level, regional and relational communities can intersect in ways that create conditions for families and children that are systematically different from the rest of the country. For example, in southern India, a large body of research has found that the norms of this region, in contrast to the norms of northern India, “provide women more exposure to the outside world, more voice in family life, and more freedom of movement than do the social systems of the north” (Jejeebhoy, 1995). In fact, recent research findings refute the notion that differences in women’s autonomy in South Asia can be ascribed to religious differences (with the main suggestion that Hindu women are more autonomous than Muslim women); these findings show that the north-south regional differences are much more salient (Jejeebhoy & Sathar, 2001). Women’s autonomy itself is determined largely by women’s education, which is much more accessible in southern regions of India, such as the state of Tamil Nadu (Jejeebhoy, 1995; Jejeebhoy & Sathar, 2001), we know that women’s autonomy influences the opportunities for optimal ecd (UNESCO, 2007).
including France and Sweden, and on par with others such as Australia, Canada, Spain, and Germany. However, after taxes and transfers, the United States has the highest poverty rate among all OECD nations, at 18%, between 6% and 11% higher than all other OECD nations (with the exception of Australia, which has a post tax and transfer poverty rate of 16%) (Smeeding & Ross, 1999). Prior to transfers, poverty rates across OECD nations were consistently high, with a range of 32% in Italy to 8% in the Netherlands. However, after governments applied redistributive measures, the rates for lone mothers are reduced to approximately 10% in many OECD nations, with a low of 4% in Germany. By contrast, the poverty rate for lone mothers in the United States averaged at 16% (Boujan & Liu, 2005).

A randomized controlled trial in Mexico (Gertler, 2004) integrated access to cash transfers with improvements in children’s physical health and has shown much success. PROGRESA (renamed OPPORTUNIDADES) is a national programme designed to mitigate the effects of extreme poverty and socioeconomic inequalities in child well-being. The programme involves giving cash transfers to families, provided that children aged 0–60 months are immunized and attend well-baby visits where their nutritional status is monitored. They are given nutritional supplements, and their parents are given health education. Pregnant women receive prenatal care, lactating women receive postpartum care, other family members receive physical check-ups once per year (where they also receive health education), and adult family members participate in regular meetings where health, hygiene, and nutritional issues are discussed. An evaluation of this study found that children born during the two-year intervention period experienced 25% less illness in the first six months of life than the control children, and children aged 0–60 months during the intervention experienced 39.5% less illness than their counterparts in the control group. Children in the PROGRESA (renamed OPPORTUNIDADES) programme were also one fourth as likely to be anemic, and grew one centimeter more, on average. Finally, the results of this study suggest that the effects of the programme were cumulative, increasing the longer the children stayed in the programme (Gertler, 2004).

**KEY MESSAGES: REGIONAL AND NATIONAL**

1. Monitoring variation in children’s developmental outcomes at the regional level provides insights regarding “nurturant” macro-environmental conditions.

2. Effective governance for ECD programs and services generally takes place at the regional level.

3. “Indirect” (social/economic) policies that affect ECD are also often enacted at the regional and national levels.

4. National governments must be held responsible for upholding their commitments to the CRC and the MDGs.

5. Investing in ECD is an integral component of a nation’s long-term economic and social strategy; underinvestment in ECD undermines societal progress.

6. “Child and family friendly” societal investment strategies can be enacted regardless of the relative level of the per capita gross domestic product (GDP) of a society.

7. Requirements of international conventions, such as the CRC, International Labour Organization (ILO) Global Reports, and Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), can be used as levers for change at the national level.

8. Child survival and ECD are inseparable; investments that bolster ECD tremendously increase child survival while simultaneously improving the future life chances of all children.

**The Global Level**

It is often difficult to characterize globalization, let alone its influence on children. There are many types of stakeholders that shape the global environment, including nation-states, multilateral economic organizations, industry, multilateral development agencies, non-governmental development agencies, and civil society groups. The global environment can influence ECD through its effects on the policies of nations. A major feature of the global environment in relation to children’s well-being is the element of power in economic, social, and political terms. Power differentials between types of actors, and particularly between nations, have many consequences, including the ability of some nations (mainly resource-rich ones) to influence the policies of other nations (mainly resource-poor ones). It follows then that the ability of resource-poor nations to enact policies that are optimal for ECD may be compromised though this requires further direct evaluation. Efforts to enable nations to gain independence over their own futures, and encouragement of multilateral aid to favour policy directions that benefit children are major elements in promoting ECD. Notwithstanding this, most of the recommendations in this report are within the capabilities of any national government that meets the international criteria for a “competent authority.”

One well-known set of policies that was introduced to many resource-poor nations in the 1990s and early 1990s was the Structural Adjustment Programme (SAP) of the World Bank and International Monetary Fund. The purpose of SAP was to increase the economic prosperity of low-income nations for the purpose of paying debts to high-income nations. SAP involved increasing privatization and decreasing the role of the government in many aspects of national economic and social endeavours, including reducing investments in social welfare programmes, such as education, health care, and other services that benefit ECD, as a means of increasing “efficiency” and spurring economic growth in the resource-poor nations. Ghana’s experience with structural adjustment is briefly described here. It is particularly compelling, since it is often viewed by international agencies as perhaps the most successful case of structural adjustment in Africa.

Ghana’s SAP commenced in 1983 and involved reducing government expenditures by cutting social services, a post tax and transfer poverty rate of 60% (Beaujot & Liu, 2005)

A randomized controlled trial in Mexico (Gertler, 2004) integrated access to cash transfers with improvements in children’s physical health and has shown much success. PROGRESA (renamed OPPORTUNIDADES) is a national programme designed to mitigate the effects of extreme poverty and socioeconomic inequalities in child well-being. The programme involves giving cash transfers to families, provided that children aged 0–60 months are immunized and attend well-baby visits where their nutritional status is monitored. They are given nutritional supplements, and their parents are given health education. Pregnant women receive prenatal care, lactating women receive postpartum care, other family members receive physical check-ups once per year (where they also receive health education), and adult family members participate in regular meetings where health, hygiene, and nutritional issues are discussed. An evaluation of this study found that children born during the two-year intervention period experienced 25% less illness in the first six months of life than the control children, and children aged 0–60 months during the intervention experienced 39.5% less illness than their counterparts in the control group. Children in the PROGRESA (renamed OPPORTUNIDADES) programme were also one fourth as likely to be anemic, and grew one centimeter more, on average. Finally, the results of this study suggest that the effects of the programme were cumulative, increasing the longer the children stayed in the programme (Gertler, 2004).

**Efforts to enable nations to gain independence over their own futures, and encouragement of multilateral aid to favour policy directions that benefit children are major elements in promoting ECD.**

The global environment is also characterized by important declarations that affirm the rights of children (CRC, 1990) and of women (United Nations Division on the Advancement of Women (CEDAW), 2007), which, by extension, influences the well-being of children. In particular, the new General Comment #7 on Implementing Rights in Early Childhood of the CRC (2005) creates an opportunity to hold “state parties” responsible for the physical, social/emo-
tional, and language/cognitive development of young children, as well as eradicating child labour. Other sections of the CRC also have varying degrees of relevance to ECD. For example, Article 6 explicitly decrees that state parties (which primarily refers to nations) are responsible for ensuring “to the maximum extent possible … the development of the child.” CEDAW “was adopted in 1979 by the [United Nations] General Assembly, [and] is often described as an international bill of rights for women” (United Nations Division on the Advancement of Women, CEDAW 2007). Since the convention is aimed at improving the circumstances of women, it clearly has implications for the well-being and development of children. In addition, the Global Monitoring Report from UNICEF ties Education for All to ECD.

One of the most alarming concerns for today’s children is the issue of child labour. Data from 2002 compiled by the ILO suggest that approximately 246 million children are engaged in some form of child labour, which is defined as most productive activity of children, but “excludes the activities of children 12 years and older who are working only a few hours a week in permitted light work and those of children 15 years and above whose work is not classified as ‘hazardous’” (2002). Of these, 171 million child labourers were working in hazardous situations or conditions. The overwhelming number of child labourers (over 173.7 million) is concentrated in the Asia-Pacific region, followed by Sub-Saharan Africa (48.8 million) and Latin America and the Caribbean (17.4 million). Among child labourers, boys slightly outnumber girls (132 million versus 113 million), but even more disproportionately (95.7 million compared to 74.8 million) bear the burden of work that is characterized as hazardous (ILO, 2002).

The use of children to perform labour in order to produce commodities to be sold on the market is certainly nothing new; however, the world’s capacity to ameliorate child labour has increased (although we may not always act on this capacity), primarily owing to more avenues for advocacy and institutional support for the protection of child well-being. Article 32 of the CRC makes it imperative that state parties recognize the right of the child to be protected from child labour, particularly work that is harmful to her or his development.

The world’s capacity to ameliorate child labour has increased, primarily owing to more avenues for advocacy and institutional support for the protection of child well-being, e.g. Article 32 of CRC.

The role of civil society

At the global level, the role of non-governmental international bodies and civil society is critical for creating the economic, social, and political conditions that support ECD and children’s welfare more broadly. Civil society makes a particularly strong contribution to ECD and population health. Civil society groups are conceptualized as being organized at, and acting on, all levels of social organization, from local residential environments; and to increase the capacity of citizens, and the support of political institutions in promoting expressions of civil organization. When civil society is enabled, there are many avenues through which it can engage on behalf of children. Civil society groups can initiate government, NGO, and community action on social determinants of ECD. They can advocate on behalf of children to ensure that governments and international agencies adopt policies that positively benefit children’s well-being. They can be instrumental in organizing strategies at the local level to provide families and children with effective delivery of ECD services; to improve the safety, cohesion, and efficacy of residential environments; and to increase the capacity of local and relational communities to better the lives of children. Although research on the direct effect of civil society on ECD is limited, the strong statistical association between the

The international community needs to agree on valid ways to measure ECD that are analogous to existing global measurements of health and human development, such as Infant Mortality Rates (IMR), Under Five Mortality Rates (U5MR), stunting, and the Human Development Index. This is essential to achieving national and international recognition of the scale of the ECD challenges we face, and to establishing credible international goals. We are currently able to measure IMR and U5MR across whole societies in a valid, reliable, and credible fashion. As a result, individual states and the global community recognize the scale of the child survival problem and have set the MDGs to address it. Similarly, the level of early childhood nutrition across populations is estimated through rates of stunting. This act of measurement, too, has led to national and international recognition of the scale of the problem, and an MDG has been set. The problem is that we have no comparable indicator for ECD, and therefore no measurement, no data, no data, no problem, no problem, no action. Creating a global measurement system to monitor ECD needs to be an essential component of every nation’s ECD strategy. Now that signatory countries are required to report progress in fulfilling General Comment # 7 of the CRC (Implementing Rights in Early Childhood), there is an incentive for the international
Discussion and Recommendations

A child requires nurturant conditions to thrive. The process of development is influenced not only by a child’s nutritional and health status but also by the kind of interactions—beginning in utero—infants and children develop with caregivers in their environment. We know that early environments influence individual children’s development independent of and in combination with their biologic characteristics, and there is a growing awareness of specific periods in children’s brain development that affect health outcomes over a lifetime.

Enriched environments and the quality of stimulation, security, and support during sensitive periods of development are of utmost importance from conception to eight years of age. The environments responsible for fostering nurturant conditions for children range from the intimate realm of the family to the broader socioeconomic context shaped by governments, international agencies, and civil society. These environments and their characteristics are the social determinants of ECD.

In order to assist key stakeholders in their pursuit of creating the conditions that support early child development the evidence leads us to make the following recommendations.

CREATION OF A GLOBAL ALLIANCE FOR EARLY CHILD DEVELOPMENT

While governments can do much to change the circumstances of the world’s children and families, this review has also demonstrated the need for global collaboration in the area of ECD.

1) We propose an expanded global interagency collaboration—the Global Alliance for Early Child Development (GAECD)—that will build upon existing informal networks of agencies currently working on ECD internationally, such as UNICEF, UNESCO, The Consultative Group on ECCD, World Bank, The Bernard van Leer Foundation, Sorous Foundation, the Aga Khan Foundation and the WHO.

It should work towards linking ECD to the Millennium Development Goals, especially to poverty reduction, education, gender equality, and child survival.

THE WORLD HEALTH ORGANIZATION’S UNIQUE CONTRIBUTION TO EARLY CHILD DEVELOPMENT GLOBALLY

1) The WHO has a critical role to play in advocacy for ECD as a key social determinant of health that must be addressed beyond the Commission on Social Determinants of Health.

2) In their commitment to ECD and to equity, the WHO should recognize that ECD is a key social determinant of health playing a critical role for achieving the Millennium Development Goals by subsuming its child survival and health programs globally under the developmental perspective articulated in this report.

3) The WHO should be responsible for provision of technical support for the inclusion of ECD policies within national development policies and in the national development frameworks/instruments (SWAPS, PRSP, Fast Track Initiatives, etc)

4) The WHO should provide technical support to regions, countries and partners for the integration of simple ECD interventions such as the IMCI Care for Development intervention in health services and in community health initiatives.

5) Assessing the costs and benefits of ECD programmes remains a challenge but WHO should take responsibility for gathering data on the effectiveness of interventions, especially those that are connected to the health care system.

6) The WHO should commit to overseeing an interagency collaboration for scaling up ECD programmes through district health systems in several countries to develop models and dissemination of the findings to all countries.
Early Child Development: A Powerful Equalizer

Discussion and Recommendations

GENERATING THE NECESSARY COMMITMENT AT MULTIPLE LEVELS OF SOCIETY

1. Local, regional, and national governments should incorporate the “science of early child development” into policy.

2. In order to achieve a global consensus on the importance of ECD, there is a need to foster a broader and more profound understanding of what is involved in ECD, and to a much wider audience than in the past. This should take shape as a social marketing campaign that expands to include audiences not traditionally thought of as ECD stakeholders: finance and planning departments of government, the economic sector, the corporate world, and media.

3. The GA-ECD should be responsible for ensuring broad dissemination of the science of ECD in conjunction with the social marketing campaign.

4. Governments, by ratifying the Convention on the Rights of the Child, have committed themselves to realizing rights in early childhood. Implementation pilots, like those in Jamaica, are designed to raise consciousness among families, communities, service providers and policy makers about rights in early childhood, and should be a model for how to conduct such campaigns in other countries.

5. There must be a fully funded global capacity building strategy to assist countries in incorporating the science of early child development into policy; and implementing and monitoring rights in early childhood under the UN Convention on the Rights of the Child.

STRUCTURAL REQUIREMENTS FOR IMPLEMENTATION

1. Governments should create an inter-ministerial policy framework for ECD that clearly articulates the roles and responsibilities of each sector and how they will collaborate. Governments should also integrate ECD policy elements into the agenda of each sector to ensure that they are considered routinely in sectoral decision-making. Governments will need to reallocate resources to decrease inequities in access to high-quality ECD programmes and services; to facilitate this, our review has identified evidence that can be used as a benchmark for judging the quality of ECD programmes and services.

2. Children benefit most when national governments adopt child- and family-friendly policies that guarantee adequate income for all, maternity benefits, financial support for the ultra-poor, and allow parents and caregivers to balance their time spent at home and work. Governments should take up the challenge of creating a work-life/home-life balance, by putting systems in place to ensure that quality out of home community-based childcare relevant to local culture and context is available for the children of working mothers.

3. In order to have the appropriate capacity/inrastructure to tackle issues related to ECD, governments, in association with international agencies, should create interdisciplinary opportunities for professional training and research in ECD in resource-poor countries. This could be achieved through regional centres of excellence such as that emerging at the Aga Khan University in Karachi, and/or distance education models such as the ECD Virtual University.

4. Community involvement is an important component of successful ECD programming. Because of this, governments should involve local communities in developing, implementing, monitoring and reviewing ECD policies, programmes and services. This does not absolve governments from their responsibilities but ensures stronger relationships between government and the local communities where service delivery occurs.

5. STRATEGIES FOR IMPLEMENTATION

1. Given the overlap in underlying determinants, governments should be building upon an established child survival and health programmes to make ECD programs accessible through existing platforms. The health care system is often the most cost-effective platform and most universal point of contact.

2. Governments need to develop strategies for “scaling up” effective programmes from the local to the national, without sacrificing the characteristics of the programme that made it effective. Implementation integrity and accountability at the local level must be sustained, even when programs are scaled-up to the national level.

3. Governments should ensure that children are enrolled in school, that gender inequities in years of schooling are eliminated, that schooling is free and compulsory.

4. UNICEF, with the concurrence of the GA-ECD, should develop a common formula for calculating national expenditures on ECD, as well as per capita investment in children. An economic analysis that indicates the “return on investment” that society can anticipate from different types of ECD programs and services should be created and disseminated.

MONITORING PROCESSES AND OUTCOMES RELATED TO ECD

1. There is an immediate need to expand the evidence base related to ECD programmes, services, policy and evaluations in resource-poor countries where systems are stressed, resources are low, and challenges of basic living are high. It is not acceptable for inferences made from research conducted in resource-rich countries to be applied to resource-poor countries. Essential in this evidence base are economic analyses of the effectiveness of ECD programmes and services as they occur in resource-poor countries.

2. An essential precondition for ECD is the child’s basic right to a name and a nationality; thus, national governments have an essential predisposing role to play by ensuring that all children are registered at birth, through maintaining a functioning, comprehensive birth registry without financial costs to families for registration.

3. We now understand that the transactional nature of young children’s relationships are far more important for their growth and development than has traditionally been recognized. Children do not just grow up according to internal laws of biology; they grow and develop through the interplay of human relationships in the environments where they live. In order to provide nurturant environments for their children, all families need support from community and government. The quality of support received by families should be monitored by local NGOs including community groups and parents’ committees as part of the reporting under the CEC. The goal is universal access to a range of ECD services: parenting and caregiver support, quality childcare, nutrition, social protection, primary healthcare, and basic education—preschool through school-age. To be effective, these services need to be coordinated at the regional level, and delivered at the local level in a way that puts the child at the centre.

4. National governments and international agencies should be responsible for funding independent monitoring of ECD programmes and services for quality and effectiveness. This should include an assessment of barriers to and opportunities for access, with a particular focus on decreasing inequality in ECD. Mechanisms need to be developed and implemented to ensure that communities and central agencies work together to collect reliable data on outcomes.
Conclusions

What a child experiences during the early years sets a critical foundation for the entire life course. ECD, including physical, social/emotional and language/cognitive domains, strongly influences basic learning, school success, economic participation, social citizenship, and health. The principal strategic insight of this document is that the nurturant qualities of the environments where children grow up, live, and learn matter the most for their development, yet parents cannot provide strong nurturant environments without help from local, regional, national, and international agencies. Therefore, this report’s principal contribution is to propose ways in which government and civil society actors, from local to international, can work in concert with families to provide equitable access to strong nurturant environments for all children globally. Recognizing the strong impact of ECD on adult life, it is imperative that governments recognize that disparities in the nurturant environments required for healthy child development will impact differentially on the outcome of different nations and societies. In some societies, inequities in ECD translate into vastly different life chances for children; in others, disparities in ECD reach a critical point where they become a threat to peace and sustainable development. The result of our efforts suggest two primary directions for the future:

1) Continued research to provide a better understanding of the effects of environments on biological embedding and ECD, particularly of broader environments.

2) The use of available information to inform action to further the goal of a “grass-roots to global” child-centered social investment strategy.

Appendix A: Critical Appraisal of the Underlying Evidence

Elsewhere, it has been convincingly argued that, for several reasons, the traditional hierarchy of evidence may not be suitable for “appraising the evidence for social or public health interventions.” One particular case in which this is especially true is in the search for evidence concerning social determinants of health. That traditional evidentiary hierarchies are incompatible (or, at least, not completely compatible) with the available and desirable types of information in this area is supported by the prominence given to measurement and evidence issues by the WHO’s CSDH. The evidence gathered by the Knowledge Network for Early Child Development (KN-ecd) draws on several notions of what constitutes valid and reliable “evidence.” The aim is to provide meaningful ways of weighing the available data and information in the field. The following provides an overview of the manner in which evidence was weighed for inclusion in this report. It is organized according to the “spheres of influence” outlined in the TEAM-ecd framework, since “types of evidence” cluster along these lines as well.

At the level of the individual, much of the recent evidence that is available in the literature has developed out of the broad acceptance of the CRC. With children recognized as fully human beings with evolving capacities to contribute to their lives, researchers have also recognized the value of including children’s perspectives in knowledge generation. A major limitation in interpreting this body of evidence (yet also its strength, in that it is methodologically appropriate) is that the small sample sizes and nature of qualitative research limits the generalizability of the work. Despite this scientific limitation, the moral and ethical value or obligation to consider the wishes/ perspectives/needs of children in this evidence was paramount. We therefore do not make broad claims that extend beyond the evidence; rather, we suggest that, from the body of literature regarding children’s perspectives, children deserve to be considered social actors, and that it is our duty to consider their views in our work. The bio-physiological responses to environmental stimuli that result in developmental outcomes for young children have undergone numerous and rigorous investigations. This is especially true compared to the body of knowledge regarding biological–environmental interactions for adults. Our knowledge of “biological embedding” comes from well-controlled experimental conditions that have been completed both in primates (including humans) and non-primates. In this way, information at this level meets the traditional “gold standard” of evidence.

With the family as a sphere of influence, the evidence-base is virtually void of experimental evidence. This is largely because it is neither feasible nor ethical to randomize or control family conditions. There are exceptions to this, such as experimental (or quasi-experimental) evidence obtained from studies of siblings and orphans. Where possible, these studies have been included. For the most part, studies conducted about the effect of family characteristics/structure/parenting on children have been observational. Within observational research, both descriptive studies (e.g., ecologic and cross-sectional studies) and analytic studies (e.g., cohort studies) have been completed. Wherever possible, results obtained from cohort studies were favoured over those obtained from descriptive studies. In comparison to cross-sectional studies, cohort studies enable the establishment of temporal order: that the cause arose before the outcome. At the family-level, there was also an explicit desire to demonstrate population-level patterns between socioeconomic conditions and child development, and moreover, to demonstrate variation in these patterns across populations or societies. Therefore, at this level, for this

The following programmes and services are presented as examples of “good practice” towards creating nurturant environments in a diversity of contexts.

Linked to Health Care Systems

INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS (IMCI)
The WHO’s IMCI program seeks to reduce childhood mortality, illness, and disability as well as promote health and development among children aged 0–5 years. IMCI has both preventive and curative aspects, which are designed to be implemented at the level of the family, the community, and through the health system. IMCI prioritizes the proper identification and treatment of childhood illnesses within a variety of settings, including homes and health facilities, but also provides counselling for parents and caregivers, and referral services for severely ill children. The main implementation involves the following steps:

- adopting an integrated approach to child health and development in the national health policy
- adapting the standard IMCI clinical guidelines to the country’s needs, policies, available drugs, and to the local foods and language
- upgrading care in local clinics by training health workers in new methods to examine and treat children, and to counsel parents effectively
- enabling upgraded care by ensuring a sufficient supply of the right low-cost medicines and simple equipment
- strengthening care in hospitals for those children too sick to be treated in out-patient clinics

Appendix B: Examples of ECD Programmes and Services

The following programmes and services are presented as examples of “good practice” towards creating nurturant environments for children. In some cases, the examples were chosen to support a particular point, such as with the Kangaroo Care; in other cases the inclusion was based upon the availability of information on the programme or services. We endeavoured to include the highest quality programmes and services where available.

For the studies included in the regional, national, and international spheres, scientific rigour was much more difficult to ensure. As mentioned in the broader TEAM-ECD evidence document (Siddiqi, Irwin & Hertzman, 2007), this is largely due to the lack of studies conducted at this level. The literature review yielded very little experimental information, of which the primary example is the PROGRESA (renamed Oportunidades) study. Beyond that, most of the information gathered comes from cross-sectional or other forms of descriptive observational studies. These studies, though they don’t provide definitive evidence, were included because they make strong suggestions about future areas to be investigated, and because there are strong plausible links between micro-levels for which we have data (such as the family) and macro-environments such as the national, the regional, and international environments. In traditional scientific terms, plausibility is often assessed in biological terms. We contend here that what is apparent is a sociological plausibility.

In order to maintain a social determinants of health perspective on the evidence we included in this report, in the ECD programmes and services section, rather than provide a “laundry list” of specific ECD programmes and services that have evidence of effectiveness, we chose to present generic characteristics as well as strategic and organizational principles of quality and sustainable programmes that are transferable around the globe. One rationale behind this decision is that, despite the best evidence of a programme or service’s effectiveness, we cannot support the practice of taking a successful program or service from one context and expecting it to work as effectively (or at all) in another context. What we can support is consideration of generic characteristics and principles that have crossed contexts, or characteristics of nurturant environments that we know have been proven to support children’s development.

To answer the question of criteria for inclusion of examples of programmes and services in this report, we turn to many sources: 1) to our ECD experts who have been on the ground and experienced the effects of particular programmes—this includes the notion of “best practice”; 2) to the grey literature; 3) to the evidence of program and services effectiveness; and 4) to consideration of whether programs meet the criteria which we articulate in the ECD programmes and services section for creating nurturant environments for children. In some cases, the examples were chosen to support a particular point, such as with the Kangaroo Care; in other cases the inclusion was based upon the availability of information on the programme or services. We endeavoured to include the highest quality programmes and services where available.

Evidence for the residential and relational communities, for similar reasons, arises primarily from prospective cohort investigations. Studies chosen for review were those which arose from the strongest research designs; those which were the best controlled, and most free of other forms of bias, as judged by the assessments in which they appeared and their known scientific reputation in the field.

In order to maintain a social determinants of health perspective on the evidence we included in this report, in the ECD programmes and services section, rather than provide a “laundry list” of specific ECD programmes and services that have evidence of effectiveness, we chose to present generic characteristics as well as strategic and organizational principles of quality and sustainable programmes that are transferable around the globe. new mothers who require more information, which has shown significant impact on breastfeeding success. In the region, women’s literacy level is generally low, especially in rural areas. The program’s aim is to bridge the gap between tribal and cultural patterns and beliefs about breastfeeding, child nutrition, health, and development; and the practice of correct breastfeeding, by providing support for consistent, high-quality information on breastfeeding. This cde point of contact provides an opportunity for parents to access lactation consultation and early childhood education classes. The mid-term evaluation of the project, in the form of a KAP (Knowledge/Attitude/Practice) study revealed that the cde’s involvement in the breastfeeding and nutrition education efforts in the region significantly improved mothers’ knowledge, which led to their health promoting behaviours in terms of their children’s health and nutrition. Further evaluation is still required to provide evidence about the impact of the program on children’s developmental outcomes.

NURSE HOME VISITING

Kazakhstan

Through its existing nurse home visiting system, Kazakhstan has introduced an ecd (early childhood education) model, to increase parents’ understanding of their children’s psycho-social and cognitive developmental needs—without additional costs. The Care for Development Module of the imc Training Package, jointly developed by [UNICEF, UNICEF, and UNICEF] and the European Union, was used as the basic training package. The project is supported jointly by [UNICEF, UNICEF, and UNICEF] and is carried out under the leadership of the Kazakhstani Ministry of Health. It builds on the country’s existing ecd, and aims at improving the capacity of service providers. During implementation, the program involves local medical training institutions, local administration, and community participation. Nurses visit newborn babies almost every week during the first month, and regularly afterwards. A Healthy Life Style Center is also involved in knowledge development, training, monitoring, and evaluation. The Healthy Life Style Centre is a para-governmental training centre with strong academic links to medical and social research institutions. This program has recently been evaluated and the report will be available soon. This program, and several similar initiatives supported by international NGOs, the World Bank, and others, can play an important role in furthering Kazakhstan’s cde reform.

Australia

Maternal and child health/care nurses visit young children regularly over the first 5 years of life in Australia. and one of the goals of this activity is to promote ecd. In addition to monitoring development and responding to any parental concerns about development and behaviour, many nurses provide anticipatory guidance and suggest ways of promoting development. They run first-time mothers’ groups, and provide parents with a range of written materials about ecd. (Department of Health and Aged Care. (1998) A healthy start for 0-5 year olds. Department of Health and Aged Care Occasional Papers Series, No. 3. Commonwealth of Australia.)

COMMUNITY DEVELOPMENT EMPowerment (cde)

The Community Development Empowerment (cde) Program in Malaysia was established to address the needs of children and families in resource-poor communities in an attempt to improve the environment within which children are raised. cde includes the following activities:

• expanding preschool programs with emphasis on stimulating cognitive, physical, and socioemotional development

• health care workers conducting meetings with community members to identify and map the existing formal and informal services that meet the particular needs of families

Once identified, the priorities for the communities are to establish a childcare program and immunization plan for young children, as well as income-generating activities for women and single mothers. Parents participated in the development and coordination of the interventions, such as pediatric assessment, educational services, intervention services, and childcare coordination. A major feature of the program is to strengthen the links between parental values, the community’s social structure, and the hcs. This program builds on existing community resources and has been shown to be cost effective. cde addresses children’s particular ecd needs in combination with health care services and programs, and supports mothers to engage in income-producing activities.

REACH OUT AND READ (ror)

Reach Out and Read (ror) is a U.S. national non-profit organization that promotes early literacy by giving new books to children and advice to parents attending pediatric examinations about the importance of reading aloud. ror programs make early literacy a standard part of pediatric primary care and as such are a point of contact with the hcs, one that has proven to support children’s early development. Following the ror model, physicians and nurses advise parents that reading aloud is the most important thing they can do to help their children love books and to start school ready to learn. Pediatricians and other clinicians are trained in the three-part ror model in an effort to promote pediatric literacy:

1. At every well-child check-up, doctors and nurses encourage parents to read aloud to their young children, and offer age-appropriate tips and encouragement.

2. Providers give every child between the ages of six months and five years new, developmentally appropriate children’s books to keep.

3. In literacy-rich waiting room environments, often with volunteer readers, parents and children learn about the pleasures and techniques of looking at books together.

Research findings evaluating the impact of ror’s efforts have been remarkably consistent. Compared to families that have not participated in ror, parents who have received the ror intervention are significantly more likely to read to their children and have more children’s books in the home. Most importantly, studies examining language in young children found an association between the ror intervention and statistically significant improvements in preschool language scores, a good predictor of later literacy success.

There are currently ror program sites located in all 50 states, the District of Columbia, Puerto Rico, the U.S. Virgin Islands, and Guam. ror programs are housed at hospitals, health centers, and private pediatric practices. (Source: http://www.reachoutandread.org/index.html)

INTEGRATED FAMILY-BASED ECD (IFBCED)

In Thailand, several local and international organizations, for example, UNICEF, Christian Children’s Foundation, and Save the Children, in collaboration with Department of Health in the Ministry of Public Health and local universities, have supported the development of the Integrated Family-Based ECD (IFBCED) project, which has been in effect since 1996. The project operates from health and health centres and involves collaboration between experienced mothers (who volunteer as ambassadors), the hcs, and the broader community (e.g., universities, other educational centers, not-for-profit organizations).

Each ambassador works with five families in her neighbourhood and provides the mothers with information and advice about child

14 Former existing programs like the Australian model can be found in many countries; the scope and age range of the states may vary.

Appendix B
health, nutrition, and development in a range of settings such as in peoples’ homes or at a local market. Monthly training sessions (on issues such as family life, child development, infant care, etc.) and meetings are held in local departments of health to update the ambassadors on how to change information and materials in relation to children health and development. The approach is especially useful because older children frequently provide some care for their younger siblings or neighbours in Thailand. The ambassadors also provide necessary information about the importance of child health, nutrition, and developmental issues to these older children. In one of the more “hands-on” lessons, students in the 5th and 6th grades work with and learn from the ambassadors about how to determine the vaccination status and developmental progress of the younger children in their families. All these educational and training initiatives are coordinated through the Ministry of Public Health. In this case positive programme evaluations resulted in expansion of the programme to ages 0–18 years but in doing so the programme became diluted and is no longer functioning. (Herscovitch, L. (1997) Moving Child and Family Programs to Scale in Thailand: Integrated Program for Child and Family Development. Bangkok, Thailand: UNICEF.)

IMMUNIZATION

Expanded Programme on Immunization (EPI)

The WHO’s Expanded Programme on Immunization (EPI) was originally launched in 1974, at a time when less than 5% of the world’s children received immunization against the six most easily preventable diseases: diphtheria, tetanus, pertussis (whooping cough), polio, measles, and tuberculosis. Over the past 30 years, the EPI has increased its coverage to the point where there are now an estimated 250 million immunization contacts with children around the world on an annual basis. Disease prevention is a major component of reducing child mortality, and the long-term international success of the EPI has resulted in significant and measurable reductions in preventable disease. The long-term success and scale of the EPI is now providing a framework within which to introduce other children’s health services.

The scale of the WHO’s EPI, as well as its near-universal coverage, are now being recognized as potentially valuable opportunities with which to bundle other child health promotion activities. The time at which 90% of the world’s children receive immunization, usually within their first two years of life, this is a potential contact point for other health interventions or monitoring. Kenya has been especially proactive in utilizing this early contact point. The Kenyan Ministry of Health has recently decided to collect information about developmental indicators during immunization visits as a way of monitoring the progress of ECD in Kenya, on a population basis. Immunization visits are also viewed as an opportunity to distribute information about ECD and infant health to parents (personal communication, Annah Wamie). Other innovative projects that use immunization visits as the key contact point within the health sector include the large-scale distribution of insecticide-treated bed nets in Togo, designed to further reduce the spread of diseases like malaria.

The importance of universal immunization programs, both in terms of reducing childhood disease and providing opportunities for additional early childhood interventions, should not be underestimated. Immunization programs are often reliant upon a combination of public, private, national, and international funding sources, and as such these programs often compete with other programs and priorities of national health agendas. While the 30-year history of EPI has yielded worldwide success, variations and fluctuations in immunization coverage at the national level indicate the difficulty involved in maintaining the universality of immunization programs. (www.afro.who.int; www.unicef.org/health/files/UNICEFTechnicalNoteMalariaImplementationApproach1.doc)

In Absence of Health Care Systems

Early Child Development: A Powerful Equalizer

In Nepal the Equal Access programme (EAP) also discuss topics like safe motherhood, nutrition, and immunization. (Source: Early Child Development Services (ICDS))

Another similar initiative in India, Integrated Child Development Services (ICDS), is a multi dimensional, community based effort aimed at improving the quality of life of women and children living in poverty. The programme grew out of the recognition that all infants require developmental assessment, and that the established immunization clinic offered a point of contact with the HCs. As such, a more comprehensive early childhood development program was established. The clinics function in connection with health facilities’ during babies’ immunization visits, mothers are given information about development, a Developmental Observation Card (DODC) to help them monitor their infant’s development, and an opportunity to seek detailed assessment guidance if necessary. The aim of the plan is to empower families, in particular mothers, to learn more about their children’s health and developmental issues by offering on-site education and the possibility of follow-up home visits. As immunization programs become coupled with other child health services, such as early childhood interventions and ECD monitoring, there may be increased opportunities to find permanent public funding for these programs.

The Equal Access Initiative uses appropriate and low cost technology (satellite broadcast, AM/FM broadcasts) and community outreach to disseminate information to families living in remote rural areas. Equal Access creates customized communication strategies and outreach solutions on a range of topics including prevention of HIV/AIDS, women’s health, and early childhood development. By designing and producing compelling local language audio and multimedia programs in-country, the program educates and catalyzes behavior change in target audiences.

A new ECD radio program called Kheldei Siksha (“Learning While Playing”) is now broadcast in Nepal via FM and satellite radio to ECD centers and a broadcast audience of millions. Kheldei Siksha helps parents and communities create positive environments for children under the age of six. Through the program, parents learn about the importance of their children’s intellectual and emotional development. This educational program reaches out to parents and workers in children’s centers with ways to better identify, address, and support the needs of children. By bringing together educators, parents and trained ECD facilitators, “Learning while Playing” transforms the underlying lack of knowledge about early childhood development that perpetuates cycles of poverty throughout Nepal. While frankly discussing and contextualizing the impact of child rights, play-based learning, and parental and community roles in a child’s education, the programs work to transform the way in which children’s early education is conceived and implemented. A large part of this effort is working with educators and parents to move beyond the traditional rote teaching methods often referred to as the “three R’s: Reading, Writing and Arithmetic” and to convince parents that quality play-based programs, stories, and songs are appropriate, valid, and accelerate children’s intellectual development. Additionally, the programs use interviews with community members and education specialists, as well as songs and stories, to transform the identity of educators, the government, and—most importantly—the parents of young children throughout Nepal, by creating an understanding of the appropriateness and long-lasting positive benefits of ECD programs for children prior to attending primary school. Episodes also discuss topics like safe motherhood, nutrition, and immunization. (Source: 1997 Global Immunization. Annual Review of Public Health, Vol 13, pp 233-237.)
The Women’s Development Project worked to promote various development initiatives for women in five provinces of Lao PDR. After five years, interest developed and a need was identified to more directly address child development issues. The Early Childhood and Family Development Project (ECFD) grew out of this experience. Project Planning Workshops for ECFD were organized in villages in the initial steps of development and implementation. Village-level planning resulted in agreement on needs and objectives, an understanding of overall design, assessments of resources and constraints, activity planning, setting up the project committee, and criteria for selecting village volunteers. The community-based curriculum development process focused on participatory input at the local level to create a curriculum that could be adapted to the particular needs of different ethnic groups. The process focused on village data collection and needs assessment. Analysis of existing traditional knowledge was used as a basis for curriculum development. One of the most unique activities in the Lao PDR experience was a village engagement agreement signed by village members and the village development committee. It was based on a child rights framework and included actions that could be taken immediately while waiting for needed external assistance. (Description taken from: Programming experiences in ECD, First edition, November 2006, UNICEF p. 23, and World Bank, Early Childhood Counts: Programming Resources for Early Childhood Care and Development (CD-ROM), The Consultative Group on ECD, World Bank, Washington DC, 1999.)

Appendix B

Appendix C: Population-based Measurement of Early Child Development from a National Perspective

In the international development community, there have been multiple efforts to assess social welfare in ways that facilitate comparison across societies. To date, many approaches have been developed, each with its own set of assumptions regarding the factors that contribute to, and reflect, well-being. The World Health Organization (WHO) Commission on Social Determinants of Health, Knowledge Network on Early Child Development, proposes that early child development (ECD) is an outcome (or rather, a set of outcomes) that is fundamentally reflective of the social success of societies. ECD is also an indicator of future societal success, as it is associated with learning skills, health, and other measures of well-being throughout the lifespan; as such, it can be considered a fundamental measure of the potential for societies to flourish in multiple social domains. The extent to which a nation provides opportunities for healthy child development is the extent to which the well-being of its most vulnerable members is supported.

Prior literature suggests that individuals within societies are differentially affected by adverse conditions such as lower levels of GDP, high levels of income inequality, and the like. We suggest here that children are often a vulnerable group, due to a variety of factors, from their stage of biological development, to their compromised ability to exercise life choices. Knowledge of ECD levels in a society provides a direct measure of societal welfare by highlighting well-being during the early years, but in the process also addresses societies’ future prospects for well-being. Thus, we are promoting population-based measurement of ECD with the aim of constructing a globally accepted social indicator.

Despite an extensive literature review, we have been unable to locate prior efforts to frame ECD in this manner. The reason seems to be that, until now, ECD research has been an individual-oriented field, dominated by psychological and educational approaches and focused on curriculum and programme implementation strategies. The advent of the Knowledge Network on ECD, under the auspices of the WHO, provides an opportunity to add a different perspective—the population health perspective—to the mix. Population health sees ECD as a social determinant of health, requiring that we come to understand, through acts of measurement, where systematic differences in the prospects for healthy child development are emerging among clearly defined populations of children around the world. Once identified, these systematic differences become the basis for understanding the modifiable determinants of ECD, for measuring progress in ECD over time, and for measuring equity of access to the conditions that support healthy child development.

Coming to agreement on an internationally comparable ECD indicator will not be easy. The indicator must meet the following criteria:

- encompass those domains of early child development that influence health, well-being, learning, and behaviour across the lifespan
- be based upon a common international conception of the relevant domains of ECD, consensus as to the specific elements within each domain that must be measured the same way everywhere in the world, and recognition of those elements that are distinct in different contexts
- notwithstanding the above challenges, be transferable to diverse global contexts, recognizing that the conditions under which children are dying are the same conditions under which children are living
- provide valid and comparable information for children of a given age, regardless of whether or not they are in school

Appendix C
In light of these challenges, the ecd indicator cannot be a single attribute, like infant mortality; instead, it must tap into multiple attributes of child development. Perhaps the most notable successful precedent on the international stage to date is the Human Development Index (hdi), introduced by the United Nations Development Programme (undp) in 1990. The hdi assesses the status of societal welfare using a composite score based on three measures: life expectancy, adult literacy, and purchasing power adjusted per capita gross domestic product. It is fair to say that the hdi has had a marked influence on discourse regarding international development. With respect to ecd, the multiple attributes must be broad enough to meet the first criterion above; that is, to encompass those domains of early development that influence health, well-being, learning, and behaviour across the lifecourse. In practice, there are three broad domains of development that meet this criterion: physical, language/cognitive, and social/emotional.

The process of reducing such diverse domains as physical, social/emotional, and language/cognitive development to a single, transferable, and comparable index is known as “commensuration.” That is to say, by reducing each domain to a number, we can then compare them directly with one another and, by reducing these numbers to a single multi-attribute index, we can compare ecd across societies, just like we currently do with infant mortality. Calls for commensuration are obviously controversial and have caused intellectual divisions for as long as there has been intellectual discourse. For example, Plato was in favour of commensuration and Aristotle was opposed to it. Not surprisingly, this division is alive and well in the ecd international development community today. The four criteria listed above reflect a compromise between—on the one hand—the need to succeed in an act of commensuration, in order to allow ecd to compete with other childhood priorities (like survival) on an “epistemologically level playing field” while—on the other hand—not letting the reductionist tendency necessary for commensuration to somehow defeat global diversity by making ecd appear to be a matter of “one size fits all.”

Appendix D: Children and Families in Global Perspective: Discussion of and excerpts from Heymann’s Forgotten Families

Introduction

With the tremendous connectedness of people and societies worldwide, a global perspective on the issues facing children and their families is critical. There are two primary factors that serve as the impetus for a global lens of examination. First, that with greater links between societies comes better information about the state of people and their environments everywhere. Second, that with increased complexity of the global economy, the policy decisions made in one nation or region have far reaching implications all over the world. In these regards, the work of Jody Heymann has made major contributions. Studies conducted by Heymann’s Project on Global Working Families have ranged from in-depth interviews of more than 1,000 families in Latin America, Africa, Asia, North America, and Europe, to analyzing survey data on 55,000 families around the world, to examining the extent of public policies supporting working parents and their children in 180 countries. The following are some highlights from Forgotten Families: Ending the Growing Crisis Confronting Children and Working Parents in the Global Economy (Oxford University Press, 2006). More information can be found at www.mcgill.ca/ihsp/.

Popular Misconceptions on Caregiving for Young Children

One of the primary ways in which the global economy affects children and families is through the patterns of caregiving that prevail under various societal circumstances. “When you ask the leaders in most countries who is caring for infants, toddlers, and preschoolers, they have similar answers: ‘Grandparents play a large role in our culture.’ When pressed, they make clear that they mean grandmothers. What about when grandmothers aren’t available, you ask? ‘There’s lots of informal care,’ they inevitably reply, ‘other family members, neighbours, women in the community.’ Many mothers can bring their children to work.” The answers are vague because they describe a world that has been kept out of sight, unexamined.

[When stating to a large teaching hospital in Gabarone that] we were looking at the conditions that working families face a hand went up. “Those issues don’t affect us here. Everyone has extended family members they can rely on so they never have any problem getting care for their children.” Though the belief was satisfying, the problem was that the experience of the families we had interviewed in Botswana belied it. We interviewed many families in which parents had no choice but to leave young children home alone, pull older children out of school to provide free care, or take children to the workplace even when doing so threatened the children’s health and development or the parents’ jobs. But before I could respond to the fantasy the first speaker relayed by sharing the experiences of some of the 250 we had already interviewed, a Motswana surgeon raised his hand and interjected: “A lot of parents have no one they can rely on. I see the children who, because of that, end up being left home alone when they come into the emergency room or into my operating room with broken bones and burns.”

Empirical Findings on Caregiving Patterns for Young Children

Extended Family

“What, then, is the global reality? There is no doubt that both having two parents in a nuclear family and having extended family can make an enormous difference to children’s care. Among families we interviewed, 30% of single parents had left their young children home alone compared with 2% of parents living with a spouse or partner. When...
single parents have no other adult caregivers in the household, young children are even more likely to be left home alone (56% versus 35%). But the myths that extended families alone solve the problem are mistaken in at least three ways. First, many working parents and their young children have sporadic, limited, or no contact with extended-family members they might ever turn to for help. Worldwide, with urbanization and the increasing mobility required to get and keep jobs, the number of working adults who live near enough to their own parents to be able to turn to them for regular assistance is rapidly declining.

“Second, even among those who continue to live near their children’s grandparents, many cannot rely on them for help. Grandparents themselves may need work and may be as constrained as parents in their ability to provide routine care or even to take time off to care for a grandchild who is sick. Third, all too often those adult family members who might be able to help—because they are close by and are not working themselves or already caring for a full house—face physical and mental health constraints. In fact, when extended family members are close, they are as likely to be in need of care as to be able to assist with it.”

When extended family is not an option

“In situations where extended-family members are in need of care, preschool children often get less care than if no extended family were nearby. When mothers or fathers are caring for other sick family members, children are twice as likely to be left home alone. Forty percent of working parents caring for a sick spouse and 4.3% of parents caring for extended family had to leave a child home alone (compared with 2.5% not caring for a sick spouse and 2.1% not caring for sick family members). When extended-family members don’t require assistance, they may still be too physically limited, frail, or sick to provide adequate care for their grandchildren, nephews, nieces, and other dependents because the same constraints on age and health that limit extended-family members’ ability to work affect the quality of the care they can provide.”

Further, these factors are patterned by parents’ socioeconomic resources. “Low-income parents are less likely to receive help from and more likely to need to provide caregiving assistance to extended family.” 13% of those parents earning less than $20 per day (purchasing power parity adjusted) can rely on extended family for help (and do not need to provide assistance to them) compared to 45% of those parents earning more than $10 per day. 47% of parents earning fewer than $10 per day (purchasing power parity adjusted) need to provide assistance to extended family compared to 42% of those earning more than $10 daily.

Parents taking their children to work

When family is unavailable, another common global response is parents taking their children to work. “While some policy makers acknowledge the improbability of such care in factories and the unlikelihood that parents will be given permission to bring children to work elsewhere in the formal sector, they assume it is not only possible but a decent solution in the informal sector.” The image conjured up is of a parent—nearly universally a mother—working with an infant swaddled tenderly on her back or a toddler playing happily at her side as she sells goods in a market or cleans a home. … In our studies, we met many women who had lost formal sector, decent paying jobs in order to care for their children. …

“At times, they subsequently found informal sector jobs which allowed them to bring their children, but even those women, who had the better experiences of the lot, did not have any romanticized fantasy of their children’s lives spent at their mother’s side. Most shared a bleak view of children at work with their mothers who had started in the informal sector because of lack of education and job choices and had never been able to leave because of caregiving responsibilities.

“Even when children taken to work are not at high risk of sustaining sudden life-threatening injuries, their opportunities for normal growth are often degraded daily. Amalia Montoya, born and reared in Cancun, Mexico, was raising her son as a single mother. She had been caring for her cleaning house since age fifteen and never had the chance to finish school. Living far from her family, she had no one to turn to for help. Without sufficient public supported slots available, childcare was far beyond her economic reach. Amalia took her infant son to work with her because she had no other choice. It was really difficult because it’s not the same as being in your own house. When he began to cry because he was hungry, I couldn’t tend to him at the same time as working.” … She went on to describe how she grew depressed over the situation and her son’s consequent malnutrition.

“Beyond Amalia’s inability to feed her son regularly, she couldn’t care for him adequately when he was sick. When Amalia gained access to a childcare center, perhaps the most telling summary of her son’s experience was her delight in the most basic elements: ‘I dropped him off at seven-thirty in the morning and picked him up at five o’clock in the afternoon. He ate there and everything.’ She was grateful even for care that consisted of the most fundamental features: enabling her to work, providing her son with adult supervision, and ensuring that he could eat.

“The same stories echoed among the parents we interviewed in Botswana and Vietnam. What differed across national borders and economic circumstances was not the nature of the problem but the level of the parents’ desperation. … This is also similarly patterned along socioeconomic lines. One in four parents earning less than $10 dollars per day (purchasing power parity adjusted) have to take their children to work regularly, as do one in four parents who have only primary or middle-school education themselves. Parents who work in the informal sector are the least likely to have access to formal childcare, as a result, half of the parents we interviewed who worked in the informal sector needed to bring their children regularly.”

Informal care

“(Another) fiction about preschool childcare is that inexpensive informal care is a viable solution. It’s clear that low-income families and many middle-income ones cannot currently afford or find space in formal childcare programmes for their young children. But it’s also clear that there is a large and apparently less-expensive informal sector for care. Public policy makers turn to informal care, without beginning to examine the double standard implied as they support formal early childhood care and education programmes in higher-income nations, isn’t informal care the solution for young children in poor countries?” These experts argue that it is less expensive and assume it is as good as formal care. Our experience is that, in the majority of cases, parents reported only that it was cheaper. …

While in theory, care provided by adults in informal care settings could be of equal quality to formal settings, this was not the common experience of most parents we interviewed, and in particular, this was not the experience of low-income families. Though many countries have some degree of subsidy for low-income families using formal child care settings, far fewer subsidies and little public provision or supervision exist in informal settings. As a result of this and of parents’ low wages, those low-income parents using informal care typically could afford to pay little. This resulted in their having extremely limited choices in childcare providers. The low wages they could afford to provide meant that, in general, they were hiring either adults who could not find other work or adults who provided the informal care while working at another job. The low skill level of those hired and the fact that those hired were, at times, simultaneously doing other work led to poor-quality care when it was provided. Moreover, problems that began with the poor quality of childcare providers in the informal sector were exacerbated by the lack of supervision in the informal sector. Parents repeatedly recounted stories of going home to find that informal childcare providers had left their children home alone for all or part of the day.

“In countries we studied, many parents reported that they had to leave their young children in the ‘care’ of other children. In Vietnam, 15% of the working parents we

Early Childhood Development: A Powerful Equalizer

Conclusion

Governments have begun to employ potential solutions. Vietnam, with a higher availability of public childcare services, had, overall, more families with access to formal childcare as well as the smallest differences across income groups in use of formal childcare. “Fifty-seven percent of lower-income families in Ho Chi Minh City were able to send a child to formal childcare, as were 62% of higher income families.” In Mexico, the government has a mandate to provide childcare for employees in the formal sector to help narrow income disparities. The figures show that, indeed, the gap in the use of formal childcare between poorer and middle-income parents is less in the formal sector, where child care is part of social security (48% compared to 53%) than in the informal sector (38% compared to 21%).

“When young children are left home alone or in substandard care, the potential for tragedy is real.” This includes the risk of children suffering accidents or emergencies while their parents are at work and becoming the victims of violence. “But there is another, slower, but equally devastating type of tragedy that is transforming the lives of tens of millions of preschool children. Unable to find or afford decent care, needing to work and only finding jobs under the worst conditions, these parents are forced to leave their preschool children in care which jeopardizes their health and development as well as their safety. The quality of the care they receive is so poor that with each day that passes, their health and development slowly deteriorate, and their life-chances decline further.”
