What are the measles vaccination coverage gaps?

New Technologies to Support Measles Elimination
GVIRF, Johannesburg, South Africa
15-17 March 2016
Peter Strebel, WHO, IVB/EPI
Main Points

• High level measles control has been achieved
• However, progress has slowed and we are off track with respect to achieving GVAP goals
• The immediate problem is gaps in vaccination coverage
• The solution must include stronger programme management and accountability combined with new tools and tactics
• Simpler vaccine delivery method for use by volunteers in house-to-house vaccination would be a "game changer"
High level measles control has been achieved

Annual reported cases and MCV1* and MCV2** coverage, 1980-2014

* MCV1 coverage: coverage with first dose of measles-containing vaccine as estimated by WHO and UNICEF.
**MCV2 estimates is only available from 2000 when global data collection started, however some countries have introduced the vaccine earlier.

194 WHO Member States.
Updated on 15 July 2015
The Region of the Americas has eliminated measles and rubella.
The Report Card
Global Vaccine Action Plan mid-point targets

- **DTP3**: All countries >90% national coverage and >80% in every district by **end 2015**
- **Polio**: transmission stopped by **end 2014**
- **Maternal and neonatal tetanus**: eliminated by **2015**
- **Measles**: eliminated in 4 regions by **end-2015**
- **Rubella**: eliminated in 2 regions by **end-2015**
- **Introduction of under-utilized vaccines**: At least 90 low or middle income countries to have introduced one or more such vaccines by **2015**
63% of countries have reached \(\geq 90\%\) coverage

Immunization coverage with 1\(^{st}\) dose of measles containing vaccines in infants, 2014

Date of slide: 16 July 2015
Routine coverage has plateaued in Africa

Regional MCV1 coverage (WUENIC) and number of countries achieving 90% MCV1 coverage. 2000 – 2014
Children are also being missed in campaigns

WHO/IVB database, data reported to WHO by member states as of 7 September 2015
WHO/UNICEF national coverage estimates, 2014 revision, data as of July 2015
Current strategies are reaching 4 of 5 children.

The 5th child is harder to reach due to:
- Geographically remote
- Living in urban slums
- Civil war
- Migrants, refugees
- Vaccine hesitancy

This graphic highlights the problem that underlies the failure to reach GVAP goals.
Research/Recherche

Evaluation of house-to-house versus fixed-site oral poliovirus vaccine delivery strategies in a mass immunization campaign in Egypt

R.W. Linkins,¹ E. Mansour,² O. Wassif,³ M.H. Hassan,³ & P.A. Patriarca⁴

Among poliomyelitis eradication activities recommended by WHO are national immunization days. Most campaigns have delivered oral poliovirus vaccine (OPV) from fixed sites, reaching 80–90% of target populations. Although house-to-house vaccination provides nearly universal coverage, countries have been reluctant to use this approach because it is considered more costly and logistically difficult. To quantify the cost-effectiveness of both these strategies, we compared the vaccine coverage and vaccination costs per child for house-to-house and fixed-site delivery in a mass campaign in Egypt. While personnel and total costs were higher in house-to-house delivery (38% and 13% higher, respectively), the costs per child vaccinated were similar. This was due primarily to the high coverage levels achieved in house-to-house delivery (100% versus 86%) and the reduced vaccine wastage. Vaccinating children at highest risk of infection was only 25–50% as expensive on a per child basis using house-to-house delivery, since such children were less likely to visit fixed sites. These findings may not be generalizable to other countries where labour costs are higher and the population density lower; however, house-to-house delivery may prove to be the most cost-effective eradication strategy by ensuring universal access to immunization.

Innovation is needed

1. Adapt polio tactics for reaching zero dose children
   • Use of mobile phones, GIS mapping

2. Simpler vaccine delivery method for use by volunteers and in house to house vaccination

3. Rapid field diagnostic test

4. Rapid assessment of immunity
   • Individual susceptibility
   • Population immunity gaps
Summary

- While high level measles control has been achieved, progress has plateaued.
- The immediate problem is gaps in vaccination coverage.
- The solution must include **stronger programme management and accountability** combined with **new tools and tactics**.
- More investment in research that is programmatically oriented is urgently needed.
