What is the rate of decay of maternal antibodies against measles in infants born to mothers with vaccine-induced immunity compared to mothers with immunity acquired from disease?

Umid Sharapov, MD, MSc
CDC/Global Immunization Division
Introduction

There’s a previous review article published in 2000 by Caceres VM, Strebel PM, Sutter RW “Factors Determining Prevalence of Maternal Antibody to Measles Virus throughout infancy: A review”
Objective

To conduct a literature review to determine the rate of decay of maternal antibodies against measles in infants born to mothers with vaccine-induced immunity compared to mothers with immunity acquired from disease.
Materials and methods

• Search criteria similar as in the Caceres and *et al* review paper

• MEDLINE, Embase, CINAHL

• Period: 2000 to May 2015

• Key words: measles, maternal, antibody, and decay
  • Retrieved 126 abstracts
  • Eligible for review 5 articles
  • Only one reported decay rate in a prospective study
Definitions

• Half-life of an antibody is the amount of time needed for antibody concentration to decrease by half compared to its initial concentration.

• Decay rate of maternal antibodies - is the constant ratio for the concentration of antibodies decay in a given period of time compared with the total amount of antibodies present at the beginning of that period.

• Key determinants:
  – Placental transfer
  – Level of maternal measles antibodies at birth
  – The rate of decay of maternal antibodies

• Maternal measles antibody half-life 40-64 days
  – Two papers reported steeper decay curves in infants with higher maternal measles antibodies at birth

• Seroprevalence studies main objectives are to determining target age group, not antibody decay rates
Seroprevalence of maternal antibody to measles virus in infancy by country

Proportion of infants of vaccinated women and naturally immune women still immune as a function of time to loss of immunity *

Proportion of infants of vaccinated women and naturally immune women still immune as a function of time to loss of immunity. Shaded area is 95% confidence interval

Proportion of infants of vaccinated women and naturally immune women still immune as a function of time to loss of immunity * (continued)

• The median time to loss of immunity:
  – 3.78 months for infants of naturally infected mothers
  – 0.97 months for infants of vaccinated mothers

• By 6 months of age, >99% of infants of vaccinated women and 95% of infants of naturally immune women had lost MMA according to the model

Maternal measles antibodies in communities with high and low vaccination coverage**

\[ \chi^2 = 42.979; \, P = 0.000. \]

Limitations

• Testing methods and definitions of protection used varied among studies
  – Hemagglutination inhibition test, plaque reduction neutralization test, ELISA

• Mothers vaccination status documentation, possible boosting

• Many studies focused on seroprevalence vs decay
Summary

• Half-life of maternal measles antibodies ranges from 35 to 64 days in the recent studies

• Duration of protection: from 3.5 in infants born to mothers with vaccine induced immunity, and 5.5 months – born to mothers with natural induced immunity*

• Rate of decay reported as 7.77 IU/(ml year) (the concertation of maternal antibodies halves every months)

• Infants born to women with measles vaccine induced immunity receive fewer MMA and therefore have shorter protection than infants born to women with naturally acquired immunity
